

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

LECTURES
ON
FORENSIC MEDICINE;
Delivered at the Aldersgate School of Medicine,
BY WILLIAM CUMMIN, M.D.

INTRODUCTORY LECTURE.

GENTLEMEN,—The subject of the course of lectures on which we are about to enter, is one which, for variety, interest, and importance, is second to none other taught in the schools. An assertion of this kind in the outset, may possibly risk the raising of expectations which it may not be so easy in the sequel to realize: but it is proper, at all hazards, that the fact should be fairly stated.

Definition.—Forensic medicine, in its literal sense, signifies medicine, or medical science, adapted to the forum or court of justice; but its actual import may be more largely described. As at present generally understood, it comprehends all that medical knowledge which is available for the ascertainment of facts required in the administration of justice, and that information which is requisite for the construction of certain laws. An unexceptionable definition cannot readily be given. I might quote to you the various forms in which the best authorities, both at home and abroad, have endeavoured to describe and to define the object of this study; but it would not be a very profitable mode of spending our time; the terms already employed may perhaps be deemed sufficiently clear and adequate for every purpose. As an art, forensic medicine assists in law-making as well as in the administration of the laws; it comes in aid of the legis-

Other appellations.—The distinctive appellation of Forensic medicine—*medicina forensis*—has been sanctioned by Latin writers for more than a century, and has been freely adopted in various countries; particularly in Italy and Spain. As a synonym, Legal medicine—*medicina legalis*, *médecine légale*—is used principally by our French contemporaries, and is, perhaps, in some degree, a preferable term to that used among us, as more obviously implying an immediate relation to law. The Juridical or Judicial medicine of some authors, though it approach in signification to the *Gerichtliche Medicin*, *G. Arzneikunde*, *G. Arzneiwissenschaft*, of the Germans, cannot be considered as a very correct title; for medical men are never called on to declare what is or is not the law; their business in courts of justice is simply to ascertain facts whereby the law, as interpreted by the proper authorities, may be duly administered. But what shall we say of Medical jurisprudence?—an unfortunate misnomer, which has obtained a footing in this country, and which began to be employed before the subject it was intended to denote was rightly understood. Medical jurisprudence is synonymous, or identical, with medical law; using the term law in its ordinary sense of legal science. Now who shall say that medical law and legal medicine mean the same thing? Might we not as well assert that the chestnut-horse and the horse-chestnut are equivalent?

But whatever be the appellation we give this study—whether forensic, legal, or juridical medicine—its nature and objects are easy to be recognized. It ministers to certain necessities of man as a member of society, just as clinical medicine does to his wants as an individual. That the duty of the medical practitioner is not confined to the sick chamber has long been known: the medical man has also to attend the court

curing or preventing disease, such a definition is now generally admitted to be incomplete, for it does not embrace the practitioner's duties in aid of the construction and administration of the laws.

History.—This, gentlemen, is no mere modern or new-fangled application of medical science; it is nearly as old as clinical medicine itself. It is not unreasonable to suppose that mankind possessed some degree of medical knowledge even before they were collected into communities: but it is not possible to believe that this event took place, and that laws were instituted for the governance of society, without the aid of some degree of medical skill in their formation, and some also in having them properly executed. A rapid glance at the history of forensic medicine will not here be out of place: it will show at how early a period medico-legal questions began to be entertained, also what sort of questions have principally occupied the attention of legislators and jurists, from the most ancient date up to the present time. But it were not possible (nor perhaps desirable, if possible) to enter largely into historical detail within the limits of an opening lecture: so that I shall have to refer you, for the principal facts and dates, to the Tabular View of the History and Literature of Forensic Medicine here drawn up for your inspection [see the Table subjoined to the lecture]. I have divided the whole series of events into two periods; in the first of which, the principles of the art may be recognized as existing, though not practised by a separate order of practitioners, or, indeed, by medical men at all, as was the case with clinical medicine itself in the beginning: the second period commences about the early part of the sixteenth century, when, by a special ordinance of the German Emperor, the intervention and assistance of medical witnesses, in certain specified cases occurring in courts of justice, were provided.

Period 1.—In relation to the first period I shall be very brief. We find, in the sacred books of Moses, the first written rudiments of forensic medicine. There are there stated certain distinctions to be observed with regard to wounds—homicide—violation—criminal abortion—diseases and disqualifications—the proofs of virginity, &c. founded on medical principles, and to be ascertained by the inquiries of persons competently skilled.

But the earliest special tract extant on a medico-legal subject is that of Galen, on the detection of persons who feign disease: this was produced in the second century of our æra*.

In the laws of the ancient Greeks and Romans there are many medico-legal provisions to be detected; yet, passing over several centuries, when we come to the great work of Justinian, the *Corpus Juris Civilis*, we are surprised to find in it no ordinance expressly requiring reference to be made to medical practitioners, and that, although the *medici* of the period were not an obscure nor an unprivileged class. The presence of midwives, indeed, was distinctly enjoined in executing the law *de ventre inspiciendo*; but there are several of the enactments which could not possibly be put in force with any regard to justice without the intervention of medical witnesses,—the *lex Aquilia*, for example, which ordered that damages should be paid for personal injuries,—and the *Lex Cornelia de sicuriis et veneficiis*, which took cognizance of homicide by weapons or poison.

It is a curious fact in the history of legislation, that at the very time Justinian in the East was intent on giving the world a body of laws that should concentrate all the civil wisdom of the age, the warlike nations in the north-western parts of Europe were engaged in a similar, but, of course, a far more rude, design. Before the election of the Merovingian kings, the most powerful tribe, that of the Franks, appointed four venerable chieftains to compose the Salic laws, and their labours were approved in three successive assemblies of the people. Somewhat later, the customs of the Ripuarians were transcribed and published; and the Visigoths were among the latest to secure for themselves one of the principal benefits of civilized society. The institutions of these untutored tribes have come down to us, and are found to contain several ordinances which must have given considerable latitude to medical authority in courts of justice. The capitularies also of Charlemagne, founded on the Salic and Ripuarian laws, are understood to go still further, and to render the evidence of medical men, in certain cases, indispensable. But the decretals of the Popes sanctioned a superior and more express discretion: in one of them, an ordinance of Innocent the Third, of the date 1209, it is distinctly provided that in a case of homicide by alleged wounds, there should be procured the testimony, or the judgment, rather, of experienced practitioners—*ut peritorum judicio medicorum talis percussio assereretur*, &c., an expression, by the way, which corresponds with that of Baldus, the celebrated jurisconsult of Perugia, who, in his commentary on the Pandects has said, that medical men were no common witnesses—they had rather a *judgment* to deliver, than their simple testimony.

* See MEDICAL GAZETTE, vol. xvii. p. 989.

Period 2.—But I must hasten to the second period of our medico-legal history, marked by the famous ordinance of the Emperor Charles the Fifth. Various circumstances conspired to this important enactment: anatomy had now for some time been freely practiced, and the superior value of medico-legal testimony, founded on the necroscopic appearances, had begun to be understood. Criminal codes had been drawn up by the bishops of Würzburg and Bamberg, in which the importance of medical evidence was not overlooked. With such aids to its cultivation and success was the *Heimgerichtordnung*, or grand criminal constitution of the empire, composed, and first published in the year 1533. I refer you to the historical table for the heads of the particular clauses which are of a medico-legal nature, only taking occasion here to observe, that by this ordinance, the presence of medical practitioners, in their respective grades, was secured in courts of justice, whenever their evidence was required for judicial purposes.

Legal medicine in France.—France followed the example of Germany: the reports and opinions of medical men were held to be indispensable in criminal processes relating to personal injuries, suspicious deaths, questionable suicides, &c.; and several French documents are extant, which were drawn up at a very early date in such circumstances. Ambrose Paré, that illustrious old surgeon, was decidedly the earliest writer of a treatise for the guidance of medico-legal practitioners. His book of *Rapports*, some portions of which seem to have appeared as early as 1575, contains a variety of precepts and maxims relating to some of the most important questions in legal medicine. On wounds, as inflicted before or after death—on the signs of suffocation, particularly in infant children—on the proofs of virginity, with reference to defecation—on impotence—on lesions of the viscera, and on various kinds of death, there are many sound rules prescribed. But it was not in this book alone that Paré treated of medico-legal subjects: in several other parts of his works we find notions of a similar description. In his 26th book he mentions the signs of pregnancy; in the 25th he gives some curious instances of feigned disorders, and of the methods by which they were detected; and in his 31st book he lays down certain principles relating to poisons, in order, as he says expressly, that the surgeon might be enabled to distinguish by certain signs the proofs of poisoning, and to give a faithful report thereof to the judges

times, and the advanced state to which the study has been brought in connexion with the names of Louis, Chaumier, Fodéré, Orfila, and others, are facts too well known to require dwelling on in this rapid sketch.

In Italy.—Italy may boast of having produced some of the earliest systematic writers on forensic medicine; and Baptista Codronchi, of Imola, is probably entitled in great measure to that precedence which has generally been awarded to his countryman Fedeli. Codronchi, in 1697, published at the Frankfurt press, his treatise entitled *Methodus iurisperita*, in which, as he says himself, some very difficult but most interesting questions are treated: among these are feigned diseases, real maladies or injuries forming grounds of excuse or disqualification, suspected poisoning, wilful abortion, legitimacy, virginity, impotence, pregnancy, &c., in short, his little book is a collection of medico-legal topics very remarkable for their date, though not discussed in any regular order. In his preface he speaks confidently, and, to all appearance, correctly, of his being the first to proceed in this track, and to set the example of a better kind of testimony than had been in use theretofore.

Five years later appeared the well-known work of Fortunato Fedeli, *De Relativitate Malorum*, Palermo 1009, in which there is certainly a wider range of subjects than is found in Codronchi's treatise. But the author seems to have had no idea of having been anticipated by any one. With conscious pride he says *id equidem profectum possum, nullis argumentis opus suspensum ante quod minus in locum veniat*. Fedeli obtained quite as much reputation as he merited by this book, a book remarkable, no doubt, for the period in which it appeared; but considering the crude nature of its contents, the Aristotelic formality with which it is composed, and the superstitious errors with which it abounds, one cannot readily assign a reason for its continuing to be so long looked upon as an authority. It went through three or four editions, and seventy years after its first appearance was thought worthy of being re-produced by a learned professor of Leipzig.

But the great medico-legal luminary of the Italians was Paolo Zacchia, a man of great learning, singular talent, and sound judgment. He was the great authority of his day; and there has scarcely been a writer since on Forensic medicine, who has not, more or less, availed himself of the rich treasures of that amazing performance, the *Questiones Medico-legales* (1621—1651). As may rea-

announced to the world, this voluminous work abounds with matter which at present is of very little practical utility: anatomy, surgery, physiology, chemistry, and therapeutics, have all been greatly altered and reformed since it was written; and the digressions, poetical passages, quotations from old histories, samples of the Aristotelian philosophy and Galenism, which prevailed at that period, have rendered it now rather a source of recreation than of profitable research.

In Germany.—Germany, though the source and birth-place of Forensic medicine, and in later times so productive of great names in connexion with the study, yet seems to have done little or nothing in a systematic way till nearly a century after Italy. It was not totally idle, however, in cultivating particular branches of the subject. The hydrostatic test, for example, by which the question of the respiration of the new-born child, in reference to the charge of infanticide, is sought to be determined, was contrived in Germany towards the latter part of the seventeenth century. Carl Rayger suggested, and John Schreyer employed it for forensic purposes. Other performances likewise of the Germans, about this time, were fraught with utility: on wounds—on the proofs of homicide—on defloration—and on alleged sorcery, writings of considerable value were produced. But it was in the subsequent century that brilliant progress was made among the Germans in Forensic medicine: then it was that they attained that mastery which they still continue to hold. It would occupy more time than we can at present afford even to enumerate the labours of Bohn, Teichmeyer, Hebenstreit, Haller (for Haller taught Forensic medicine), Ploucquet, Daniel, Metzger, Platner, and a host of others, who contributed to raise the science to a degree of importance previously little to be anticipated. But we shall have ample opportunities of adverting to the peculiar services and merits of the German jurists hereafter.

In England.—When from this review of the progress of Forensic medicine on the continent, we turn our eyes to what has taken place in England at an early date, we find almost a complete blank—scarcely a trace of the least attention having been paid to it; and morbid anatomy itself in a deplorable degree of backwardness. When the young Prince Henry, the hope of the nation, died in 1607, and it was popularly believed for a time that he had been poisoned through the contrivances of the favourite Somerset, it became, of course, an object with the physicians who attended the Prince in his last illness to give a

sufficient account of the appearances noticed after death. The pains taken to do this may be estimated from the steps adopted by Sir Theodore Mayerne, the first physician in ordinary to his Majesty, and in his time reckoned to be at the head of the profession. We find in his works a minute account of the last illness and death of Henry, drawn up both in French and Latin; to which is appended the certificate of the King and Lords in Council, attesting the satisfactory nature of the narrative, and acquitting Sir Theodore of all blame in the transaction. But the details of the *post-mortem* report are miserably meagre, and utterly unsatisfactory in a medico-legal point of view. It should be recollected that, at the time referred to, Harvey was pursuing those investigations which have since immortalized him, and shed so much glory on his country.

I must be permitted to dwell for a moment on the name of Harvey, which it is gratifying to be able to connect with the history of Forensic medicine in England. That illustrious man, however little motive there was in his time for attending to such observations, did not allow at least one physiological fact, bearing on a vitally important question of Forensic medicine, to escape him. It was known to Galen that the lungs of the fœtus were red, heavy, and dense, and that they afterwards became white, light, and of more delicate texture. Harvey, however, went much farther. The physician of Pergamus made no inference of medico-legal diagnosis; he did not even say that the change was produced *by* respiration; nay, he gives us to understand that the change in colour and texture is a sort of vital process that spontaneously takes place *preparatory* to the process of respiration. Now our great physiologist not only noticed the fact of change of colour in the fœtal lungs, but stated the true cause of the change, and suggested that this phenomenon might serve to distinguish whether the mother had brought forth still born offspring, or issue that had breathed after birth.

The passage in which this remark occurs should be highly prized by English medical jurists. It will be found in the 70th Exercitation, *De Generatione Animalium*:—"In embryo hoc tempore dissecto," says Harvey, speaking of the fœtus that has completed the fifth month of intra-uterine life, "*interiora omnia distincta et perfecta conspiciuntur: præsertim ventriculus, intestina, cor, renes, pulmones; qui etiam in lobos divisi sanguinolenti apparent, formamque debitam nacti sunt. Color autem his rubicundior est, quam iis qui aerem aliquando inspirarunt; quod pulmones, ab eo dilatati, al-*

bedinem induunt. Expe indicio facili inter-
morris, materis vitum, an mortuum fetum
pupervit illico enim ab inspirato aere,
mutatur pulmonum color; qui, etiam post
reperitina fata, idem permanet."

The work from which this passage is taken was first published in 1651, and the fact which it announces was probably observed several years previously. Now the tests for infanticide did not begin to be inquired into, even in Germany, until nearly thirty years after the date just mentioned.

I must pass over a whole century from this time before I can find any thing else particularly deserving of notice in the proceedings of practitioners and writers in Great Britain. The two Hunters at length contribute indirectly to the study: John Hunter, by his researches relative to the treatment of the drowned; and William, by his embryology, and his remarks on the signs of child murder; in which latter, however, he shews himself to be very imperfectly acquainted with the investigations of his predecessors and contemporaries. At the time that William Hunter stated his objections to the hydrostatic test, Haller and Morgagni had already pronounced their opinions upon it, had discussed the arguments *pro* and *con*, in respect to its value, and decided in its favour provided it were discreetly applied. Poncequet, also, and Daniel, had published their remarks on that test, and suggested others of their own in emendation of it; but Hunter seemed to know nothing of these things. In fact, though his tract on Child murder is still referred to as an authority, particularly by members of the legal profession, its author, when it was produced, was nearly a century behind his time, for he stated not one medico legal objection that had not been proposed and canvassed above at least 80 years before.

It was subsequent to the publication of Hunter's tract that the first systematic treatise on legal medicine was produced in this country. This was an abridged translation of Fœslius's Elements, by Dr. Samuel Farr, which appeared in 1768,—the original work of Fœslius being at that time above twenty years old! Yet such was the compendium which sufficed in England up to the present century, when a few elementary works began to make their appearance at intervals. Of late, indeed, there is not so much room to complain: we can even boast of having some very respectable treatises on Forensic medicine in our language. The late Dr. Gordon Smith produced works of considerable value, in his Principles, and his Analysis of Medical Evidence. Paris and Foubianque contributed much to the

and interesting volumes; and Dr. Beck sent us from beyond the Atlantic a most important production, which has become naturalized amongst us—constituting, indeed, at present our best book of Elements, and one that is eminently serviceable to the medico-legal practitioner.

It is now more than thirty years since an event occurred which ought to have had, as, indeed, it has had, a considerable influence in the promotion of Forensic medicine in this country. Through a strong recommendation to Government, a professorship of Medical Jurisprudence and Police was founded in the University of Edinburgh, in 1803: but for several years after, though the chair was occupied by a very able professor (the late Dr. Duncan), little attention was paid to the subject: nor did the emolumenta of the appointment much exceed the salary allowed by the crown. Of late, however, the study has been more successfully pursued, because patronized by authority; it has been enjoined in the curricula of several of our medical corporations: first in Edinburgh University partially; then, in 1829, in the College of Surgeons in Ireland; in 1830, by the Society of Apothecaries in London; and in 1831, by the College of Surgeons in Edinburgh. The London College of Physicians also, in their new curriculum, have adopted Forensic medicine; though, strangely enough, the London College of Surgeons have not yet thought proper to admit it, notwithstanding that it has become almost popularly and familiarly recognized as a department of the highest importance to the practitioner.

Indispensable to British practitioners.—The peculiar position in which medical practitioners in this country are placed, in respect to the legal tribunals, must necessarily lead to such a recognition; for there are not here—as there are in France, Italy, Germany, and other countries—persons specially appointed to the discharge of medico-legal functions; consequently, in the event of medical evidence being required amongst us, any practitioner in any manner connected with the case, or perhaps having no anterior cognizance of it whatever, may be called upon to act in the capacity of a medical jurist.

But our laws, perhaps it may be supposed, are of a different character from those of other countries: we do not here take cognizance of those minutiae on which the decision of cases in the foreign courts depends. In other words, it may be attempted to be alleged that medical aid is not essentially necessary for the administration or composition of British law.

If such an assertion be seriously made, it can easily be shown to be inconsis-

only to appeal to the history of our laws—criminal, ecclesiastical, and civil—to see how the matter really stands.

The laws of England, like our language, may be traced to various sources; they are the concentrated wisdom, not only of our own ancestors, but of those of other and more ancient nations. Our civil and canon law, which prevails in the ecclesiastical and certain other courts, is almost wholly borrowed from the codes of Justinian and Theodosius, and from the Decretals of the Popes; while our common law, based on the enactments of our Ethelberts, our Alfreds, and our Edwards, has been enriched by the experience of ages, and may fairly lay claim to the designation which has by some been accorded to it—namely, that of being the perfection of human reason. Now the civil law, already noticed in speaking of the *Corpus Juris* and the Decretals, contains many provisions of a medico-legal nature: these provisions have, many of them, been transmitted to us in their original integrity; and I can give you, as an example, the practice followed when it is necessary to ascertain pregnancy, in the conduct of civil suits. The writ called, after the Roman law, *de ventre inspiciendo*, is issued, and a jury of discreet and experienced persons is called upon to execute it. In criminal cases, when pregnancy is pleaded in bar of execution, a jury of *matrons* must give a verdict on the plea: but the usual practice has for some time been to substitute certain professional examiners instead. I might refer to many of our ancient statutes in like manner, to show that they contain clauses, the administration of which can only be, as it commonly has been, properly effected by medico-legal assistance. Take the statute 25th of Edward III. c. 2, concerning the crime of high treason, in compassing or imagining the death of the king—violating certain females of the royal family—slaying the judges, &c. The application of this statute has rarely taken place, nor could it well be conducted, without medical evidence being tendered. Or take the laws of Mayhem, or maiming, which were very ancient, or the Coventry act, according to which the guilt of the accused depended on his having, with a certain intent, inflicted peculiar wounds—such as slitting the nose, cutting out or disabling the tongue or any member: medical evidence was here also absolutely necessary. It is certainly true, that in these, or any other of our laws, there has rarely, if ever, been any mention of medical referees. But this is only consistent with the cautious reserve so remarkable in our legislation, which always chooses to leave as much as possible to the discretionary management of its functionaries;

nor is the necessity for medico-legal aid by any means lessened owing to that circumstance.

A better example of the cautious policy to which I allude cannot be afforded, than that which we find in the statute which I hold in my hands. It is the 9 Geo. IV. chap. 81, commonly called Lord Lansdowne's Act. It consists of thirty-eight sections, consolidating our statute law relative to offences against the person; and though full five-and-twenty of those sections are of a medico-legal nature, or requiring the evidence of medical witnesses, in order that the provisions of each should be duly satisfied, several of them requiring the substantiation of facts only to be ascertained by the examination of competent medical men, there is not one word, from beginning to end, explicitly referring to professional testimony: the nature of the proofs required, however, can leave no doubt as to the persons by whom those proofs are to be ascertained.

But the practice of our courts puts the matter beyond a question. Though there are among us no recognized medical jurists—no special class of medical referees—we find few trials in which persons discharging such functions are not specially required to be present, and called upon to elucidate, by their opinions, the difficulties that may arise. Observe the business on circuit: in almost all the cases occurring at the spring and summer assizes, the testimony of members of the profession is deemed of vital importance; the medical man seems to be the very hinge on which each case turns, the arbiter by whose decision the matter (frequently matter of life and death) is determined. Look, again, to that more ordinary and familiar court, the Coroner's—the important originator of further proceedings—where almost the entire business (with the exception, indeed, only of treasure trove, and wreck cases) consists of matter of medico-legal investigation. In few and rare instances can a Coroner's inquest be properly conducted without medical testimony; yet—and it is a good illustration of the non-intervention principle of our laws—though there are probably not less than five or six thousand inquests held by coroners annually, throughout the country, in almost every one of which medical evidence is indispensably required—it has been left entirely to the discretion of the coroner to procure that evidence; there is no medical man on whom he is specially authorized to call; he must exercise his ingenuity to obtain what he deems sufficient testimony, and has been frequently reduced to great difficulties in this respect, having had (until the passing of the new Medical Witnesses' Act) no remuneration to

offer to the professional man for the trouble of attending.

We thus see how, both by the construction of our law and the practice of its functionaries, we are all involved largely in the duty of aiding the furtherance of justice. There can be no evasion. The law requires the aidance of medical skill, that it may be duly administered, and that skill it may require at the hands of any practitioner in the kingdom. The legislature presumes every practitioner competent to act in a medico-legal capacity; nor may any medical man, however conscientious or scrupulous, excuse himself on the ground of his not being a medical jurist; when summoned, he must only make the best figure he can in exercise of the important functions demanded of him, or otherwise plead ignorance, and suffer accordingly in the public estimation.

Duties of medical jurists.—It is on most occasions a critical office to discharge well the duties of a medical jurist. Let us take a view of what is usually imposed on the practitioner, when called upon in this capacity. Suppose a case of alleged poisoning to be investigated, and that there is a party accused of that crime. The referee must in such a case bring to the investigation several requisites of a special sort. He must have a general knowledge of the effects of poisons: he must be able to distinguish the effects of poison from those of natural disease; he must be familiar with the morbid appearances produced by poison, and in nowise confound them with those resulting from other causes. By competent chemical skill he must be able to give convincing evidence of the particular deleterious substance wherewith the mischief has been done; and finally, he must be prepared to have his opinions and his processes strictly scrutinized, and to give a clear account of them *viva voce* before a legal tribunal.

Or, suppose another common case. The body of a new-born infant is found under suspicious circumstances. It will rest on the evidence of the professional examiner whether or not an indictment for murder shall be preferred against a suspected party. The competent medical jurist will in such a case proceed most cautiously and deliberately: he will examine the body, both externally and internally, with reference to several tests whereby the fact of live or still birth may be ascertained; and supposing the former to be made out, he will then endeavour to determine the cause of death. All the apparent lesions will have to be narrowly noticed; the appearances of disease or of wilful injury must be distinctly appreciated; the phe-

nomena of asphyxia by drowning, strangling, and so forth, must be carefully discriminated; and any suspicious-looking fluids in the stomach or bowels must be chemically analyzed.

In most cases of alleged unsoundness of mind,—a subject of so much interest and importance both in our civil and criminal courts of justice,—the medical referee has the arduous task imposed upon him of stating publicly his deliberate opinions respecting the existence or non-existence of such a state of mind as is consistent with responsibility for imputed crime, or competency to the management of property. He must be able to distinguish the merely eccentric individual from the person of positively unsound mind: he must define, describe, and show himself acquainted with the peculiarities constituting the various kinds of mental alienation: and here again I need not add the perils that lie in wait for the professional witness who is not perfectly prepared for the task,—the misadventures that have occurred are matter of common notoriety.

So again with respect to wounds or other personal injuries, the skill of the medical jurist will often be exercised. The question may be as to the consequence of the alleged injury—whether, in case death has followed, such a result was to be considered as inevitable or accidental; and cases of this kind sometimes involve some of the most complicated inquiries.

Special education and discipline necessary.—Without a previous and an especial discipline in the inquiries relative to which he may have to appear in a court of justice, the medical witness must not be surprised to find himself in an awkward, if not a very dangerous, situation. Even the ablest practitioners,—men the most distinguished in particular departments of medical science,—have been foiled and humiliated when they have ventured unprepared to give medical evidence. The case of John Hunter will serve as an illustration. On the trial of Donellan, in 1781, for poisoning the young baronet, his brother-in-law, the great physiologist was summoned as a witness, being presumed to be well acquainted with the action of poisons on the animal economy. I shall not trouble you with the examination and cross-examination of Mr. Hunter, but the judge's remarks must not be omitted:—"For the prisoner," said his Lordship, "you have had one gentleman called, who is likewise of the faculty, and a very able man. I can hardly say what his opinion is, for he does not seem to have formed any opinion at all of the matter. He at first said he could not form an opinion whether the death was or was not occasioned by the poison, because he could conceive that it might be

ascribed to other causes. I wished very much to have got a direct answer from Mr. Hunter, if I could, what upon the whole was the result of his attention and application to the subject, and what was his present opinion, but he says he can say nothing decisive."

I am aware that attempts have been made by some of the ardent admirers of John Hunter to defend the evidence he gave on this trial; but there is reason to believe that this is more than that eminent man himself ever ventured to do. On the contrary, he seems to have ever retained an unpleasant consciousness of the uncreditable figure he made on the occasion, and to have regretted that he had not previously taken the trouble to make himself better acquainted with the points on which he was examined. The candour, indeed, which he displayed subsequently, ought to go far towards disarming censure, while it conveys to us a lesson not to be lightly prized. He used ever to lament, as we are informed by Sir Astley Cooper, that he had not made more preparation for this trial: "he found himself a good deal embarrassed on the occasion; the lawyers took advantage of his embarrassment, and he used to express his regret publicly in his lectures, that he had not given more attention to the subject, before he ventured to give an opinion in a court of justice." This regret on the part of Mr. Hunter must have been purely for having so perilously risked his reputation, and at the same time so little served the cause of truth; for if he had given the requisite attention to the subject, he could only have come to the same conclusion as the other witnesses.

Let me be permitted to give one other example. If the most distinguished ability as a teacher of anatomy could constitute all that was requisite for a medical jurist, this was to be found in the late Mr. Joshua Brookes. Yet some circumstances which occurred in the spring of the year 1829, put his qualifications in this respect to the test. An elderly gentleman, a Mr. Neale, was found dead on the floor of his chamber; and a soldier, who had been with him the evening before, and who, there was reason to believe, had robbed him, was suspected to have been the cause of his death. The question was, whether the deceased had died a natural death,—as by apoplexy, for instance,—or had been murdered. The body was examined by Mr. Brookes, and an account of the appearances, signed by him and two other medical gentlemen, submitted to the coroner and his jury. A more unsatisfactory document cannot well be conceived issuing from men of medical education: it was, however, sufficient to lead to a verdict of

wilful murder against the soldier. But the transaction had caught the attention of the public, and luckily, also, of some well-informed members of our profession. The matter was taken up by the medical societies of the metropolis, and discussed in the journals, promptly and impartially*. Mr. Brookes had time to reconsider the circumstances of the case: he was examined again, a week after, at the Old Bailey, when the evidence he gave was directly the reverse of what he had previously given, and in consequence the prisoner was *acquitted*. It was creditable, no doubt, to Mr. Brookes to unsay what he had said before, when he became convinced of his error: but consider the appearance of all this before the public,—consider the jeopardy in which truth and justice were placed,—and what might not have been the result had there been no opportunity of retracting the original statement!

We see, then, that however the magistrate or the judge may presume medical men in general, and the more eminent among them in particular, competent to the business of forensic medicine, practitioners themselves may not so safely form the same opinion, unless they be fully conscious of sufficient preparation.

Necessity for a distinct course.—But how is that preparation to be effected? May it be attained in the course of the ordinary education for clinical practice? It is not very possible nor probable that it should. In the departments of practical medicine, surgery, midwifery, chemistry, anatomy, and materia medica, much information may undoubtedly be gathered which shall afterwards serve in the investigation of wounds, pregnancy, poisoning, and other subjects of Forensic medicine; but the special application of those branches can scarcely be expected to be entered upon by their teachers, who have already quite enough on their hands. Or if one or two of them should find time for such application, the others certainly cannot: while at all events the student is sent about gathering his medico-legal principles. There is no other feasible means save making this department of knowledge a special study,—a study which is to succeed to the student's attendance on the other branches of medical education, making this the complement and the completion of them all. There is even a positive necessity for such a course, because many of the subjects comprehended within the range of Forensic medicine are not treated of elsewhere.

Extent and variety of Forensic medicine.—If we advert to the extent and variety of topics which come within the province of

* See MEDICAL GAZETTE, vol. III. p. 578.

legal medicine, it is impossible not to be struck with the changes which some of them have undergone in course of time, some having become immeasurably lowered in the scale of relative importance, and others absolutely extinct. To give one instance: time was when *Demonology* and *Witchcraft* were prime objects of attention to the bar, the bench, and the medical profession, in this country. Some of our ablest judges were persuaded that supernatural powers of mischief were possessed by certain persons in the lower classes of society, and that they were often exercised with malicious intentions and fatal effect. The character of Sir Matthew Hale is stained by such a weakness: this great man tried prisoners who were arraigned on the charge of witchcraft; and on one occasion fortified his impressions of their guilt by appealing to one of the most learned physicians of the day, Sir Thomas Browne, who happened to be in court. It is lamentable to add, that the infatuated opinion then uttered, cost two unfortunate women their lives.

In Catholic countries, and where religious fanaticism much prevails, questions of alleged miracles often come before the authorities. Hence the consideration of miracles is still entertained by certain foreign medico-legal writers. In the work of Zacchia, we find that the first consultation in which that distinguished jurist was engaged before the Rota, was to determine whether or not the removal of epilepsy, in a certain case, was to be attributed as an instance of miraculous power to a reputed saint, whom it was intended to canonize? Tortosa, who belongs to the present century, devotes special chapters to miracles, magic, and the possessed; and Martini, one of the most eminent Italian professors of the present day, does much the same. In his *Medicina Forensis*, published so late as 1833, he treats of miracles, demoniacs, sorcerers, witches, and the bewitched. On the *delictum conjugale*, also, Martini gravely devotes a chapter to an enumeration of the circumstances under which the debtor may be occasionally excused.

If from these and similar inquiries the present advanced state of civilization in this country has wholly delivered us, it may still be doubted whether, upon that account, the circle of our medico-legal research is much contracted: the progress of knowledge, keeping pace with social improvement, has given rise to several other subjects of investigation, not less curious, perhaps, while they have far more serious claims on our attention. Toxicology may be cited as an example—a department of medical science which can scarcely be said to have originated anterior to the present

which Forensic Medicine can boast of, in connexion with this department, have already attained a perfection, which it would have been deemed by the medical jurists of the generation gone by, chimerical, if not preposterous, to hope for.

Conclusion.—I find that I must here conclude, though a number of interesting points would still deserve to be noticed. But perhaps all has been said that was absolutely essential for an opening lecture. It was my purpose to give a succinct account of the nature and the importance of Forensic medicine; and I have done this, or attempted to do it, chiefly by tracing the art from its origin. In the rapid and necessarily superficial sketch presented to you, it may be discerned at how very early a date of human society this application of medical knowledge was found requisite, and from its progress, it may be inferred how much the widely extending relations of society will in future render its assistance still more and more needed. On the actual progress—the triumphs—of legal medicine, I have dwelt but little, partly because the details can be better appreciated as we proceed in the course, and partly because, to say the truth, though there are bright and beautiful tints in the picture, there are also dark spots—deplorable blemishes. I might bring before you instances in which medical men, by the conscientious and able discharge of their duty as professional witnesses, have vindicated the purity and honour of persons unjustly charged with crime, have rescued the innocent from impending ruin, and by detecting guilt in its most secret recesses, have brought the criminal to deserved punishment. But it would be to abuse your good faith, were I, at the same time, to withhold examples of quite an opposite description, and to omit to mention in how many instances great opportunities have been lost, positive and irretrievable mischief has been done, by incompetent or reckless medical referees. That upon weighing the good against the bad, the former should be found considerably to preponderate, is gratifying as it is certain; but it would be unjustifiable hence to insinuate that the bad instances are weightless, or only as a feather in the scale. It is but too true, nor can it be too early impressed on those entering upon the study, that the practice of legal medicine involves a heavy responsibility, and that it is attended with anxieties and difficulties which do not usually fall to the lot of the ordinary practitioner. The consolation, however, is, that if the danger be great, the glory is not incommensurate, and that, in the very endeavour to achieve success, we may hope to obtain that most enviable of all prizes—the merit and contribution of one fellow

TABULAR VIEW OF THE HISTORY AND LITERATURE OF FORENSIC MEDICINE.

PERIOD I.

In which the Principles existed and were recognized without a distinct order of Practitioners.
From the earliest Date to the Sixteenth Century.

B. C.		ASSYRIANS AND EGYPTIANS.	
(3000)		The custom of exposing the sick publicly (<i>Herod. l. 107</i> , and <i>Strabo</i> .) must have led to many observations of a medico-legal kind. In Egypt, the kings themselves practised dissection, in order to discover the cause of death (<i>Plin. sts. 36</i> .) Pregnant women were respited from punishment.	
		HEBREWS.	
1773		The midwife who attended Tamar (<i>Gen. xxxviii. 28</i>) exercised a proper medico-legal discretion.	
1604		Shiphrah and Puah consulted by the king of Egypt respecting infanticide, as a measure of state policy (<i>Exod. l. 16</i> .)	
1461		Moses issues several medico-legal ordinances for investigating questions of homicide, the nature of wounds, violation, virginity, personal disqualifications, &c.: in fact, the chapters in the Pentateuch, on these subjects, contain the first written rudiments of forensic medicine.	
		GREEKS.	
884		Lycurgus ordains that the destruction of infants be regulated by certain persons, appointed to determine the question of weakness or deformity.	
505		Pythagoras; embryology—climacteric years.	
430		Democritus; signs of defecation—signs of death.	
400		Hippocrates, in various parts of his writings, touches on medico-legal subjects, particularly on seven and eight months' births, on superfoetation, &c.	
325		Aristotle, in his <i>Hist. Animal.</i> (vii. 4, &c.) states the doctrine of uncertain length of gestation in the human female; signs of pregnancy, &c.	
300		Theophrastus, on poisons: author of the celebrated work on Characters.	
230		Case of extensive poisoning by Roman matrons; above 150 of them punished.	
90		Cicero (<i>pro A. Cluentio</i> , and <i>ad Herenn.</i>) alludes to the signs of poisoning commonly noticed on the dead body.	
44		Julius Cæsar assassinated; medico-legal opinion of Antisthenes, that one wound alone, of the three-and-twenty, was mortal.	
A.D.		Germanicus dies, as it is supposed, from poison: the appearances about the body favour the popular supposition.—(<i>Nycten. Collig. l.</i>)	
19		Agrippina, with Locusta's assistance, procures several deaths by poison.—(<i>Tacit. Ann.</i>)	
54		Quintilian mentions the necessary proofs of poisoning (<i>Declam. xv.</i>) Pliny the elder, also, and Seneca, touch on the same subject.	
75		Galen—the first who wrote expressly on a medico-legal subject—on <i>Frigned Diseases</i> , and the means of detecting them. He also noticed the change produced in the fetal lungs at birth—the vitality of seven months' and the mortality of eight months' births—the signs of poisoning, and some circumstances connected with legitimacy.	
100			
		WESTERN EMPIRE.	
430		The Theodosian Code compiled: its enactments remain in force for a time.	
		FRANKS AND VISIGOTHS.	
450		The Salic and Riparian laws (enacted between A.D. 422 and 490) contain several provisions, requiring medico-legal assistance for putting them in practice: thus, in cases of wounds, homicide, poisoning, and the like, punishment was inflicted, or pecuniary penalties assessed, according to the amount of crime in the guilty party, which was ascertained in some instances by a <i>sectio vulnerum</i> .	
		at Amalé in the year 1157: upon this event, all at once the Civil Law met with universal acceptance throughout Europe, and commentators began to abound.	
		EASTERN EMPIRE.	
A.D.		Justinian's great work, the <i>Corpus Juris Civilis</i> , completed. It contains many laws based on medical principles, some of them expressly "on the authority of Hippocrates." The <i>lex Aguttia</i> , and <i>lex Cornelia de sterili et cœcitate</i> , also the principles laid down respecting retarded births and superfoetation, and more especially the enactment <i>de ventre inspiciendo, et de custodiendo partu</i> , require medical aid for their administration; in the latter enactment, the presence of midwives is enjoined, if necessary.	
524		The <i>Corpus Juris</i> , however, in the course of a few centuries, became obsolete, and has fallen into total oblivion in the West, when a copy of the Digest was accidentally found.	

A. D.

GERMAN EMPIRE.

790

Charlemagne, improving on the laws of the Franks, enacts his *Capitularies*, several of which virtually require the intervention of medical assessors.

JURISDICTION OF THE CHURCH.

1151

The *Decretals*, or body of Canon Law, reduced to order by Gratian the Monk. They receive successive additions for some centuries. Among them are many enactments, in which the necessity of medico-legal interference is plainly implied.

1209

Innocent III. decrees that in a case of homicide by wounds, medical evidence, or, as it is expressed, *judicium peritorum medicorum*, shall be obtained, for the better administration of justice.

A.D.

982

ARABIANS.

Rhases (Arrhasi) of Bagdad—the most original of the Arabian writers—treats of medical impostors, and the means of detecting them; on poisons also. His chief work, *Elchavi*, or the Continent.

1036

Avicenna (Ebn Sina); the most famous of the physicians of the East, accounted another Galen, and celebrated for his sagacity.

1140

Avenzoar (Ebn Zohr) of Seville; touches on the subject of impotence, &c.

1206

Averrhoes (Ebn Roschd) of Cordova.

GERMANY AND ITALY.

1238

The Emperor Frederic II. issues some ordinances of a medico-legal character; patronizes the schools of Italy; and sanctions the occasional practice of human anatomy.

1315

Mondini de Luzzi dissects publicly the bodies of two women at Bologna. This may be considered as the era of the commencement of practical forensic medicine. Mondini publishes a treatise on descriptive anatomy, illustrated with woodcuts.

1370

Baldus de Ubaldis, in his Commentary on the *Pandects*, points out the superiority of medical evidence. Medical men, he says, are no common witnesses—*proprie non sunt testes, sed est magis judicium quam testimonium*.—(*Digest. li. Tit. 12.*)

1492

Santes Ardoyni, and Cardinal Porzetti, write on poisons: the work of the former is very complete for the time in which it was composed: the morbid appearances produced by poisons are said to be described in it from actual observation.

1503

Death of Pope Alexander VI. by poison; his son, Caesar Borgia, escapes.

1503

The Bishop of Würzburg's *Ordinances*.

1507

The Bishop of Bamberg's *Criminal Constitutions*. Both these codes were revised, and incorporated in the Const. Crim. Carolina, presently to be noticed.

A.D.

1374

FRANCE.

The University of Montpellier procures leave to dissect human bodies, for instruction in anatomy.

1418

Valescus de Tharanta treats of poisons.

PERIOD II.

In which Forensic Medicine becomes a distinct Profession, practised in several countries by a special order of Medical Men.

From the year 1533 to the present time.

GERMANY.

1533

The Emperor Charles V. promulgates the great Criminal Code of the Empire—the *Constitutio Criminalis Carolina*,—certain articles of which expressly enjoin the magistrates to call in medical persons to give their evidence touching questions at issue. Thus, *Arts.* 35 and 36 relate to concealed delivery and child-murder, and ordain that the evidence of midwives and physicians shall be procured in such cases; *Art.* 147 is on wounds proving mortal, regarding which surgeons and other skilful persons are to decide whether death ensued in consequence of the injury; *Art.* 33 relates to assassination; *Art.* 37 restricts and regulates the sale of poisons; *Art.* 41 relates to witchcraft; *Art.* 59 provides a mitigation of the torture in the case of feeble persons; *Art.* 119, on the crime of violation; *Art.* 109, on magic; *Art.* 130, on poisoning, and its punishment; *Art.* 181, the question of live or still birth, with reference to concealed delivery; *Art.* 133, on criminal abortion, making a distinction in the crime, according as the fetus is *quick* or *not*; *Art.* 135 relates to suicide, whether effected with design of escaping punishment, or in insanity; *Art.* 134, the responsibility of physicians killing their patients; *Arts.* 149 and 164 authorize medico-legal inspection of the dead body before burial, in cases of suspected homicide, and *Arts.* 179 and 219 point out how the proofs of unsound mind are to be ascertained in questionable cases. The chief parts of this celebrated Code have been adopted by most of the Continental states in reforming or revising their Statute-books. It now only remains to give a list of the principal persons who have distinguished themselves in connexion with Forensic Medicine.

1564

Wier; witchcraft, hymen, &c.

1584

Libavius; bleeding of the corpse in presence of the murderer.

1626

Sebis; wounds, virginity.

1663

Bartholin; observes the phenomenon of the lungs of the still-born sinking, while other lungs float in water.

1667

Swammerdam explains why this is so.

1677

Rayger proposes the hydrostatic test.

1682

Schreyer actually practises the test for judicial purposes.

1691

Zeller writes against the test; and some of the faculties declare against it,—some, however, for it.

1701

Ammann; *Praxis vuln. lethal.*

1701

Valentin; *Pandectæ medico-legales*.

1704

Bohn; *De officio medici. clin. et forensis*; on wounds, the test of infanticide, &c.

1704

Becker; on death by drowning—*sine pota aqua*.

1706

Zittman; *Med. forensis, h. e. responsa*, &c.

1720

Schurig; *Spermatologia, Gynaecol.* &c.

1722

Telchmeyer; *Instit. med. legalis vel for.*

1723

Goellicke; *Medicina forensis*.

1725

Alberti; *Systema juris. medicæ*.

1731

Richter; *Digesta med. s. decisiones*.

1733

Tropaneger; *Decisiones med. for.*

1736

Hoffman; on poisons, wounds, &c.

1746

Eschenbach; *Med. legalis brev. thesibus*.

1753

Hebenstreit; *Anthropologia forensis*.

TABULAR VIEW OF THE HISTORY AND LITERATURE OF FORENSIC MEDICINE.

PERIOD I.

In which the Principles existed and were recognized without a distinct order of Practitioners.
From the earliest Date to the Sixteenth Century.

B. C.		ASSYRIANS AND EGYPTIANS.	
(3000)		The custom of exposing the sick publicly (<i>Herod.</i> i. 197, and <i>Strabo</i> ,) must have led to many observations of a medico-legal kind. In Egypt, the kings themselves practised dissection, in order to discover the cause of death (<i>Plin.</i> xix. 26.) Pregnant women were respited from punishment.

OBSERVATIONS
ON THE
TREATMENT OF VASCULAR
NÆVI MATERNI.

By E. A. LLOYD,

Assistant-Surgeon to St. Bartholomew's Hospital,
Surgeon to Christ's Hospital, &c.

THE disease termed vascular nœvus maternus is, I believe, as its name would imply, always a congenital affection: at all events, I never met with a morbid structure of precisely similar character, which had commenced after birth; not that I know of any reason why such a case should not occur. Such nœvi, however, at the time of birth, are almost uniformly of small size,—so small as in some instances nearly to escape detection; and even at this period they are remarkable for their extreme vascularity; in fact it is that chiefly which renders them distinguishable. But those which at birth are mere specks, as it were, sometimes become in the course of a few weeks, or even days, of considerable bulk, so as to constitute a formidable disease. They are liable to extend in every direction; and the larger the size they have acquired, the more are they likely to increase. I have many times seen them projecting as much on the inner as on the outer surface of the cheeks, lips, and eye-lids; and in more instances than one I have observed the bones of the head and face implicated in the disease. They have also been met with occupying a large portion of a limb, and extending deeply between the muscles. Mr. Langstaff removed (after death) the leg of a child affected with disease of this kind: he afterwards injected it, and, on dissection, found large portions of the diseased structure situated beneath the adipose membrane, and implicating in a greater or less degree the fascia and several of the muscles. A child about three months old, in the hospital, under Mr. Abernethy's care, died from hæmorrhage arising from a large nœvus in a state of ulceration, which occupied the front and a considerable portion of one side of the face, and which, at the period of birth, was very little larger than a pin's head.

It is therefore of great consequence to subject such cases to treatment at an

ment should be lost as soon as they are observed to be increasing. Moreover, as a surgical operation is generally required for the cure of the disease, and as such operations, when performed on very young children, are always attended with more or less danger, it is important that in every case the operation should be as simple and little painful as possible. In effecting the cure it is also desirable that means should be employed by which the least degree of deformity will be produced, and especially if the head, face, neck, or arms, be the seat of the disease. To point out means by which these objects may be, in my opinion, most effectually attained, is the purpose of this communication.

When any of the ordinary modes of treatment are employed for the removal of nœvi of large size, very serious consequences sometimes ensue. If the diseased structure be excised, very profuse, and in some cases fatal, hæmorrhage takes place. Mr. Lawrence states, in a paper published in the thirteenth volume of the Transactions of the Royal Medical and Chirurgical Society, part ii., page 422—"The profuse bleeding attendant on the removal by the knife of even small nœvi, is often alarming, and certainly dangerous, in the young patients who are the most frequent subjects of the operation." An infant who was born with a large nœvus, which was excised by Mr. Wardrop, expired from the profuse bleeding which took place during the operation.

Speaking of the destruction of nœvi by caustic, Mr. Lawrence observes—"It would probably be as dangerous as excision, though in a different way, in those of larger size." A case in which caustic potash had been applied to one of these tumors, situated on the chest, ended fatally, under the observation of Baron Boyer. Wedelius mentions a case in which the nœvus turned cancerous on the application of "aqua fortis*." But I may add, that modern surgeons will not be deterred from employing the remedy by any apprehension that such an effect will be produced.

When nœvi are treated by ligature, very alarming symptoms are liable to come on. Of this point, likewise, proof is to be found in Mr. Lawrence's paper, referred to above. He states, in detail-

ing the particulars of a case treated in this manner, "The infant seemed to suffer considerably when the ligatures were tied, the process being attended with considerable stretching and dragging of the surrounding skin, which was thrown into several large folds. For thirty-six hours the child was restless, crying almost incessantly, and occasionally convulsed." In a case of the same kind, which I had myself an opportunity of watching, exceedingly severe symptoms followed the operation, and continued for more than two days, so that the poor little sufferer's life was despaired of. Mr. Langstaff also informed me, that in a case of large nævus treated by him in the same manner, such violent constitutional disturbance was excited, that the child's life was for some time in the greatest danger. I may also add, that the treatment by ligature, severe as it is, will not always, as will be seen by and by, prove successful as a remedy for nævi. The same, too, may be said of their treatment by excision. I have known them recur after having been excised by the most experienced operators. I witnessed a case of the kind in Mr. Abernethy's practice. The nævus was situated on the sternum, a situation most favourable for the operation. In fact, such is their nature, that whatever may be the operation performed, I believe it will be invariably found, that if the smallest portion of the morbid structure be left behind uninjured, it will act as a "punctum saliens" (if I may use the expression), from which disease, perhaps more formidable than was excised at first, will be reproduced.

Another objection to all the modes of treatment adverted to above, is the unsightly scar which is in all cases left behind. And this objection likewise applies to the treatment of large nævi, by vaccination, a plan of treatment free from danger, it is true, but which is also very likely to fail.

With a view to obviate, as far as I was able, the inconveniences detailed above, I was induced to employ a mode of treatment, which, to me, was perfectly novel, as applied to nævi.

A few years ago I made a brief statement of my plan of treatment at one of the meetings of the "London Medical Society," and it was subsequently noticed, though in a very imperfect manner, in some of the publications

of the day. But it has been no where, as far as I have seen, accurately or completely described; and as I have subsequently had repeated opportunities of employing it, and with great success, I feel it incumbent on me, without any further delay, to place the following succinct account of it before my professional brethren. And it is the more necessary that I should do so, because, in a new edition of a surgical work since published, the plan is adverted to as possible to succeed, without (in ignorance no doubt) the slightest reference to its author, or even the most distant intimation that it had been ever attempted.

The plan to which I allude, and to describe which it will be my principal object on this occasion, consists of the injection into the substance of nævi of a stimulating, and, in some cases, almost an escharotic liquor. The success which occasionally attended the vaccination of such tumors had, I considered, established the principle that they might be cured by exciting in them inflammation, or that condition of a part, be it what it may, that sometimes leads to its absorption. To effect this end, I had tried various means; but as they were not generally successful, it is not worth while to detail them here. The failures in such instances having arisen, as it appeared to me, from the means employed not producing a sufficient degree of inflammation; and having met with a very large pulsating nævus, so situated that it could not, without the utmost danger, be removed by the knife, by the ligature, or by caustic, I resolved to put to the test the plan adverted to above. I considered it a fair opportunity to adopt this mode of treating it, because in this case the morbid structure, of which by far the greater part was subcutaneous, was soft and sponge-like—indeed so soft, that when pressed between the finger and thumb, the intervening substance seemed to shrink away; but in an instant, the pressure being removed, it re-appeared of its former size, and as erectile as ever. The nævus, which, as I stated, was of very large size, was situated on the left side of the face, extending from the angle of the lip, where it commenced, upwards to the temple, and transversely from the nose almost to the ear: moreover, portions of it occupied the eye-lids, projecting irregularly like varicose vessels, from their

inner surfaces, and its boundary was altogether very irregular. The whole thickness of the cheek was in some parts made up, as it were, of the nævus, the diseased structure being visible, and projecting as well on the inner as on the outer surface. It was, however, only at particular points that the skin and inner membrane of the cheek participated in the disease, as over the greater portion of the tumor they were unchanged in structure. But even where the skin and membrane of the mouth were unchanged, the purple colour of the subjacent disease was very visible. The nævus, when first observed at the birth of the child, was not larger than the point of a quill. It began to enlarge very shortly after birth; and at the time it was placed under treatment, it was increasing rapidly. The treatment of it was peculiarly difficult, in consequence of its great extent, and the irregularity of its boundary. The treatment consisted in injecting into the subcutaneous portions of the diseased mass a liquid composed of *spt. ætheris nitrici* and nitric acid; and in applying to the more superficial portions, or to such portions of the skin as were in a morbid state, the concentrated nitric acid. The injection did not enter very readily—by no means so readily as might have been expected, therefore much could not be accomplished at once, and the progress of cure was of necessity slow; but by persevering in the same means, one portion after another of the disease was removed, till the greater part had entirely disappeared. At this period the child was taken ill with the measles, which unfortunately proved fatal to it. It may be said, therefore, that the case is not complete; but it should be borne in mind that to the extent to which the remedy had been applied, it was successful, and thus its efficacy was established as far as it could be by a single instance. I had no opportunity of examining after death the parts that had been operated on.

One of the next cases that I operated on, was in a patient of Mr. Austin, surgeon, of Red Lion-street, Clerkenwell. The child was a few months old. The nævus was situated on the forehead, prominent, about the size of half a walnut, principally subcutaneous, and was increasing. I injected it five times. The liquid, which was the same as was employed in the former case, passed freely into its substance, and in about

seven weeks time the cure was accomplished. The effect of the injection was hardening of the part into which it entered, and as the hardness subsided the disease disappeared. Mr. Austin lately afforded me an opportunity of seeing the child, who is now about nine years old. The case is very satisfactory, the operation having been performed so long ago, and not a vestige of the disease remaining. That which was the cutaneous portion of the nævus is now quite white, and looks like a small cicatrix.

Another case, which I also injected in the same manner successfully, was brought to me at my own house, by the late Mr. John Wood, who had been house-surgeon to St. Bartholomew's Hospital. The nævus was situated on the cheek, and it was one of the cases treated in the hospital by means of the needle and ligature, and had been considered cured; but unfortunately it reappeared.

By the same treatment, too, I succeeded in curing one of the largest subcutaneous nævi that I ever saw: it was of the size of a very large orange, extending from above the angle of the jaw downwards, almost to the clavicle, and deeply into the substance of the neck; projecting also from the surrounding surface more than three inches. The mother lately said it was larger than the largest orange, and I believe she may be right.

The skin covering it was for the most part healthy, except at its most prominent part, where it put on the usual deep red and vascular appearance of cutaneous nævi. In texture it so much resembled a sponge, that when grasped in the hand it could be diminished to nearly half its size. The child resided a short distance out of town (Walworth); but I got it brought to the hospital on the operating day, when it was examined by all the surgeons of the hospital who were present, and also by many visitors, who all agreed that they knew of no means by which the disease could be successfully treated. The application of caustic was quite out of the question; and the same may be said of the ligature, and also of excision, as they could not possibly have succeeded, from the great magnitude of the disease and the depth to which it extended. The cure occupied about nine months, and the injection was at first sometimes

thrown in twice a week, but generally only once, and occasionally not oftener than once a fortnight. No unpleasant symptom followed at any time. Sal volatile was the liquid generally injected, and sometimes in an undiluted state. At first the superincumbent skin did not contract so fast as the tumor became absorbed, so that it hung like a pouch partly emptied, pendulous on the side of the neck. The red part, or that portion of the skin which was implicated in the disease, entirely lost its apparent vascularity, became white and shrivelled, without any topical application being made to it, and assumed very much the character of an old cicatrix. The rest of the skin (that covering the great bulk of the tumor) was of natural colour and texture. I lately saw the child, who is nearly five years old: he was four months old at the time that the treatment was commenced. There is not a vestige of the disease remaining, and the skin is as closely adapted to the subjacent parts as on the opposite side of the neck.

A very fine child, on whom I operated in the same manner, for a very large nœvus on the face, between three and four years ago, was lately brought to me by its mother, to show me how completely the disease had been cured. It was situated on the left side of the face, occupying the greater part of both the eyelids, a considerable portion of the cheek, and the whole of the corresponding side, as well as the front, of the nose. When I first took the case in hand, the child was three months old, and a most disgusting object: it is now a very nice looking child, and it requires very close inspection to discover that the disease had ever existed.

I have subsequently treated many other cases of nœvi of various sizes, and in various situations, by injection, without the occurrence, in a single instance, of an untoward symptom, and generally with complete success. I have cured several situated on the head, three on one child, and some very large ones on the trunk and limbs; but as the preceding cases are sufficient to prove the efficacy of the plan, under different and very formidable circumstances, it would be unnecessarily occupying time to give others in detail: I shall therefore proceed to describe more particularly the course I pursue in performing the ope-

ration. I shall also point out, as clearly as I am able, the variations which it is necessary to make in the treatment of different cases, as that which is most applicable to one is not always equally so to others; and I shall at the same time point out the great advantages which, in certain cases, I consider this plan of treatment possesses over every other. I shall, moreover, subjoin a few general observations on the nature of nœvi, and on some other modes of treatment which I have found it advisable to employ, under particular circumstances and in particular cases.

For the injection of nœvi it is necessary to have a syringe with tubes of different dimensions, capable of being changed at pleasure. This is the case because nœvi are of different sizes: into those of larger size the injection enters more readily if projected in a larger stream; in those whose size is smaller, it answers better for the stream to be in proportion small. The point of the tube should be introduced through an aperture in the skin, at some little distance from the disease, as there is then greater facility in compressing the nœvus, so as to prevent hæmorrhage. It is easy to prevent a single drop of blood being lost; and after the injection has properly taken effect, it rarely happens that there remains any disposition to hæmorrhage. Before injecting it the nœvus should be compressed, so as to empty it of its blood, and the pressure should be kept up till the instant that the fluid is projected by the syringe. The fluid should be retained in the nœvus for from five to ten minutes. This, of course, is easily effected by making pressure along the track which had been occupied by the tube of the syringe.

It is not always equally easy to inject nœvi, as they differ materially in their texture: some of them which are of a spongy structure, and of a moderate size, can be injected with facility and at once; but this is seldom the case with larger ones. There are nœvi so solid in their substance, that, whether they be large or small, it is exceedingly difficult to inject them at all. Before it can be accomplished, it is requisite to puncture them in various directions; but it should be done from a single point, so that the punctures shall proceed like radii towards one-half of the

circumference of a circle. It is likewise sometimes extremely difficult to excite in them the necessary degree of inflammation,—so difficult, that the operation is often obliged to be repeated several times, and this notwithstanding a very stimulating fluid has been employed. Moreover, a nævus may be too large, as in the cases I have adduced, to be treated all at once in the manner described above. If so, it must be divided into different sections, one, two, three, or more; and each section must be made the subject of a separate operation. But to inject the whole of even the more spongy nævi, if of moderate size, it is sometimes necessary to introduce the syringe at various points. When a nævus has been large, I have thrown the injection into three different parts on the same day; but, generally, I only make one attempt on the first occasion. By operating on only one part at first, I ascertain with less chance of inconvenience whether the liquor employed is too strong or too weak, and thus obtain information which enables me to proceed with more certainty in the subsequent steps of the operation.

Until a person has practised the operation a few times, it will be better that during the act of injection pressure should be made around the nævus, as otherwise the liquid will be liable to be forced into the contiguous cellular tissue, in which it would be pretty sure to excite inflammation, and consequent suppuration. For the purpose of making the pressure, the rim of the cover of a pasteboard or wooden pill-box, answers very well. The covers, as is well known, can be procured of almost any size; and a notch can be easily cut in them for the admission of the point of the syringe.

When a nævus is well injected it feels tense, and loses much of its spongy character; its colour likewise becomes changed, varying in some degree according to the nature of the fluid employed. The change of colour is not always very considerable, as but little of the injection usually passes into the cutaneous portion of a nævus, although the subcutaneous part of it shall be readily and fully injected. The injection is known to have taken effect by the tumor becoming incompressible, which in some cases it does in an hour or two, but in others a day or two will

sometimes previously elapse: after which it is rare for the disease to increase; but its subsequent absorption is sometimes very slow.

I am not prepared at present to recommend the exclusive employment of any one liquid as an injection for nævi. The spirit of nitric æther, with the addition of a small proportion of strong nitric acid, I have used oftener than any other; about one part of the latter to from ten to fifteen of the former. The spirit. ammoniæ aromaticus has been most efficient in some cases in which other liquids had failed. I have also employed successfully solutions of chloride of lime, of sulphate and acetate of zinc, of muriate of ammonia, of hydriodate of potash, &c. I have never used wine for the purpose; but Mr. Stauley employed it in a nævus seated on the lip, and, as he informed me, with success.

The chief advantages of the plan of treatment which I have been recommending are, that it is applicable to nævi so large, and so situated, as to be wholly irremediable by any other means; that it occasions no deformity (a point of some importance when the part affected is the head, face, neck, or arm of a female), the small mark remaining where the syringe enters being at a subsequent period scarcely discernible; that it produces very little pain, much less than any of the other modes most relied on; and that there is no constitutional disturbance of any consequence resulting from it.

I have stated, that from the effect which sometimes followed the vaccinating of these tumors, I was led to adopt the practice of injecting them; but I should also state, that having previously investigated most attentively their nature and habits, if I may use the term, I had arrived at the conclusion that they were only to be cured by means which would effect the complete removal or annihilation of the morbid structure: and I may add, that, to be competent to determine what plan of treatment is most applicable to nævi, it is indispensable to be acquainted, as far as possible, not only with their structure, to investigate which so much pains has been taken, but also more particularly with the nature of the connexion that subsists between them and the surrounding parts. From in-

attention in this respect, the most erroneous opinions have been entertained. Some surgeons still suppose (of which I have lately had evidence) that nævi consist of an enlarged artery, or vein; and in accordance with this opinion is their practice: they endeavour to compress the enlarged vessel, so as to prevent the transit of the blood through it, expecting by that means to remove the disease. For this purpose a ligature has been sometimes put on what has been supposed to be the principal vessel supplying the morbid part; and I was shown, not long ago, an instrument which had been ingeniously enough constructed to effect the same end.

I believe, however, it will be found, that, both in their pathology and treatment, such practitioners are greatly mistaken: indeed, I do not hesitate to say, that, as regards the more common forms of nævi materni, they certainly are in error. Their mistake, no doubt, arises from the success which has been known to attend a similar mode of practice in true cases of "aneurism by anastomosis;" a disease comparatively very rare.

In the nævi under consideration, there is a morbid structure to be got rid of; a structure not dependent, for its nourishment and vitality, upon a single vessel, but capable at all times of deriving sufficient blood for its subsistence, and also for its growth, from any of the vessels of the parts with which it is in immediate connexion. In Mr. Langstaff's case, to which I have adverted, "the nævus was principally supplied with blood from the muscular branches given off by the anterior tibial artery, which were greatly enlarged, and extremely numerous; it was also assisted by the external articular and the arteries given off by the popliteal, previous to its division into the three arteries of the leg." I knew a case in which the diseased structure was nearly separated by incision from the surrounding parts, and a ligature applied to every vessel that bled, but without the least permanent change in the condition of the disease. Another case, too, was treated on the same principle with caustic; a deep slough having been formed all round the nævus, which was of very large size, so as almost completely to separate it from the body,

and yet no good resulted; for after slough came away, the parts re-united and the disease remained as vascular and disposed to increase as ever. It follows, therefore, that it is no more reasonable to expect a nævus will be rid of by merely obstructing the circulation through the principal vessel which supplies it, than would a fatty or other tumor. To afford even a chance of success to any operation of the kind, the flow of blood to the contiguous parts must likewise be cut off, or at all events very much diminished. In fact, the only means that can be depended on for the effectual removal of the morbid structure, are such as at once destroy its vitality, or such as, operating more gradually, occasion its absorption: and of all the means that have been recommended to effect its annihilation by the latter process, injection is, I believe, most to be depended on. By this means a greater or lesser degree of inflammation may be excited in it, the effect of which is to change its texture, converting what was a spongy into solid substance. In this state its vascularity certainly becomes diminished, but as its vitality remains, the cause of its subsequent absorption is not quite apparent. If, however, I might venture an opinion, I would say that this thus brought very much into the condition of a foreign body, so that it comes an irritant to the surrounding parts, and, perhaps, in some degree, to the general system; the absorbents, consequently, are roused into action, which, in a longer or shorter time, removal is accomplished.

Although my advocacy of injection is so decided, yet I wish to guard against its being supposed that I altogether repudiate all the other plans of treatment which have been recommended with the same object in view.

I am well aware that there are many other means besides injection, by which that change in the condition of the tissue conducive to absorption may sometimes be very satisfactorily brought about. The principal of them are the continued use of pressure and cold; the insertion of the vaccine virus at different points of the skin covering the nævus; or more setons made to pass directly through the morbid structure itself, and the repeated application of triturated antimony, as well as of va-

other stimulating substances, to the whole surface of the morbid growth. Acupuncturation has moreover been recommended by Dr. M. Hall, and also by Professor Lallemand, of Montpellier. I have several times attempted to cure the disease by this mode, but have never succeeded. For my own part, I must say I should have been surprised if there had been a different result; because I have seen nævi not only punctured in the manner recommended, but also a most stimulating fluid injected into the punctures, and yet a sufficient degree of inflammation not produced. This has been particularly the case in nævi of more solid texture. As, however, the treatment has, in the able hands alluded to above, proved successful in a few cases, it may be considered right to give it a further trial: and the same may be said of all the measures just adverted to.

There is likewise another plan, employed, I believe, first by myself, by which I have succeeded in curing the disease; and as it operates principally by exciting the absorbents into action, I shall avail myself of this opportunity to describe it. In this plan, the advantages attending the use of pressure and of the seton are combined. By the means made use of, partial strangulation of the part is effected. Ligatures are passed through the substance of the tumor, by means of which, and pieces of bougie applied on each side, as in the quilled suture, the circulation of the part is placed under complete control. In this manner, therefore, perfect strangulation of the part might be produced, and its consequent death; but the object is to employ only such compression as will excite that degree of inflammation in it which is required to occasion its absorption. The pressure can be increased or diminished with the greatest facility, according to circumstances; and even after having been remitted, or rather intermitted, for a few days, it can be again applied, if care be taken not prematurely to withdraw the ligatures. If no more pressure be employed than is really requisite, there will be very little pain occasioned by it; but, on the contrary, if too much force be employed, suppuration will be produced, and consequently there will be attendant a greater or less degree of pain and constitutional disturbance.

I had recourse to this plan of treatment in a large nævus on the head of a child between three and four months old. The tumor projected full half an inch from the surface, and in its transverse diameter it measured nearly two inches. In twenty-four hours time the operation was followed by such inflammation and swelling, that it was necessary to loosen the ligatures. A slight degree of fever ensued; a small collection of pus also formed, which was discharged through a small opening in the centre of the tumor. After this every thing went on well, and the disease gradually disappeared. It was not necessary to repeat the operation. I have not yet had sufficient experience on the subject to justify me in giving a decided opinion on it; but from what I have seen I am inclined to believe that it is a plan of treatment which will be found very efficient in a large proportion of the subcutaneous vascular nævi. I should consider it especially applicable to such as may be situated on the cheeks or lips, as well as to those cases in which the disease projects decidedly beyond the surrounding natural surface—to those cases, in fact, in which excision, caustic, and the ligature, have been recommended as means by which the entire nævus and the superincumbent skin should be completely destroyed. A great advantage of this plan of treatment is, that it cures the disease like injection, without occasioning any deformity: the large scar which remains after most of the other modes of treatment being almost as great a blemish as the disease itself. It will also, I suspect, be found a much more efficacious mode of treatment than the seton, as usually employed.

But in cutaneous nævi—that is, in those which are seated principally in the skin, as well as in smaller ones of subcutaneous growth, the treatment by caustic is in many cases especially applicable. In the former I prefer the concentrated nitric acid as the remedy; in the latter the potassa fusa. And if, in the use of these means, proper care and caution be observed, they will, I believe, never fail. Moreover, they would be applicable to the greater number of cases that occur, if employed at a sufficiently early period, inasmuch as, as has been stated before, a very large majority of nævi

attention in this respect, the most erroneous opinions have been entertained. Some surgeons still suppose (of which I have lately had evidence) that nœvi consist of an enlarged artery, or vein; and in accordance with this opinion is their practice: they endeavour to compress the enlarged vessel, so as to prevent the transit of the blood through it, expecting by that means to remove the disease. For this purpose a ligature has been sometimes put on what has been supposed to be the principal vessel supplying the morbid part; and I was shown, not long ago, an instrument which had been ingeniously enough constructed to effect the same end.

I believe, however, it will be found, that, both in their pathology and treatment, such practitioners are greatly mistaken: indeed, I do not hesitate to say, that, as regards the more common forms of nœvi materni, they certainly are in error. Their mistake, no doubt, arises from the success which has been known to attend a similar mode of practice in true cases of "aneurism by anastomosis;" a disease comparatively very rare.

In the nœvi under consideration, there is a morbid structure to be got rid of; a structure not dependent, for its nourishment and vitality, upon a single vessel, but capable at all times of deriving sufficient blood for its subsistence, and also for its growth, from any of the vessels of the parts with which it is in immediate connexion. In Mr. Langstaff's case, to which I have adverted, "the nœvus was principally supplied with blood from the muscular branches given off by the anterior tibial artery, which were greatly enlarged, and extremely numerous; it was also assisted by the external articular and the arteries given off by the popliteal, previous to its division into the three arteries of the leg." I knew a case in which the diseased structure was nearly separated by incision from the surrounding parts, and a ligature applied to every vessel that bled, but without the least permanent change in the condition of the disease. Another case, too, was treated on the same principle with caustic; a deep slough having been formed all round the nœvus, which was of very large size, so as almost completely to separate it from the body,

and yet no good resulted; for after the slough came away, the parts re-united, and the disease remained as vascular and disposed to increase as ever. It follows, therefore, that it is no more reasonable to expect a nœvus will be got rid of by merely obstructing the circulation through the principal vessel that supplies it, than would a fatty or any other tumor. To afford even a chance of success to any operation of the kind, the flow of blood to the contiguous parts must likewise be cut off, or at all events very much diminished. In fact, the only means that can be depended on, for the effectual removal of the morbid structure, are such as at once destroy its vitality, or such as, operating more gradually, occasion its absorption: and of all the means that have been recommended to effect its annihilation by the latter process, injection is, I believe, the most to be depended on. By that means a greater or lesser degree of inflammation may be excited in it, the effect of which is to change its texture, converting what was a spongy into a solid substance. In this state its vascularity certainly becomes diminished; but as its vitality remains, the cause of its subsequent absorption is not quite apparent. If, however, I might venture an opinion, I would say that it is thus brought very much into the condition of a foreign body, so that it becomes an irritant to the surrounding parts, and, perhaps, in some degree, to the general system; the absorbents, consequently, are roused into action, by which, in a longer or shorter time, its removal is accomplished.

Although my advocacy of injection is so decided, yet I wish to guard against its being supposed that I altogether repudiate all the other plans of treatment which have been recommended with the same object in view.

I am well aware that there are many other means besides injection, by which that change in the condition of the part conducive to absorption may sometimes be very satisfactorily brought about. The principal of them are the combined use of pressure and cold; the insertion of the vaccine virus at different points of the skin covering the nœvus; one or more setons made to pass directly through the morbid structure itself; and the repeated application of tartarized antimony, as well as of various

other stimulating substances, to the whole surface of the morbid growth. Acupuncturation has moreover been recommended by Dr. M. Hall, and also by Professor Lallemand, of Montpellier. I have several times attempted to cure the disease by this mode, but have never succeeded. For my own part, I must say I should have been surprised if there had been a different result; because I have seen nævi not only punctured in the manner recommended, but also a most stimulating fluid injected into the punctures, and yet a sufficient degree of inflammation not produced. This has been particularly the case in nævi of more solid texture. As, however, the treatment has, in the able hands alluded to above, proved successful in a few cases, it may be considered right to give it a further trial: and the same may be said of all the measures just adverted to.

There is likewise another plan, employed, I believe, first by myself, by which I have succeeded in curing the disease; and as it operates principally by exciting the absorbents into action, I shall avail myself of this opportunity to describe it. In this plan, the advantages attending the use of pressure and of the seton are combined. By the means made use of, partial strangulation of the part is effected. Ligatures are passed through the substance of the tumor, by means of which, and pieces of bougie applied on each side, as in the quilled suture, the circulation of the part is placed under complete control. In this manner, therefore, perfect strangulation of the part might be produced, and its consequent death; but the object is to employ only such compression as will excite that degree of inflammation in it which is required to occasion its absorption. The pressure can be increased or diminished with the greatest facility, according to circumstances; and even after having been remitted, or rather intermitted, for a few days, it can be again applied, if care be taken not prematurely to withdraw the ligatures. If no more pressure be employed than is really requisite, there will be very little pain occasioned by it; but, on the contrary, if too much force be employed, suppuration will be produced, and consequently there will be attendant a greater or less degree of pain and constitutional disturbance.

I had recourse to this plan of treatment in a large nævus on the head of a child between three and four months old. The tumor projected full half an inch from the surface, and in its transverse diameter it measured nearly two inches. In twenty-four hours time the operation was followed by such inflammation and swelling, that it was necessary to loosen the ligatures. A slight degree of fever ensued; a small collection of pus also formed, which was discharged through a small opening in the centre of the tumor. After this every thing went on well, and the disease gradually disappeared. It was not necessary to repeat the operation. I have not yet had sufficient experience on the subject to justify me in giving a decided opinion on it; but from what I have seen I am inclined to believe that it is a plan of treatment which will be found very efficient in a large proportion of the subcutaneous vascular nævi. I should consider it especially applicable to such as may be situated on the cheeks or lips, as well as to those cases in which the disease projects decidedly beyond the surrounding natural surface—to those cases, in fact, in which excision, caustic, and the ligature, have been recommended as means by which the entire nævus and the superincumbent skin should be completely destroyed. A great advantage of this plan of treatment is, that it cures the disease like injection, without occasioning any deformity: the large scar which remains after most of the other modes of treatment being almost as great a blemish as the disease itself. It will also, I suspect, be found a much more efficacious mode of treatment than the seton, as usually employed.

But in cutaneous nævi—that is, in those which are seated principally in the skin, as well as in smaller ones of subcutaneous growth, the treatment by caustic is in many cases especially applicable. In the former I prefer the concentrated nitric acid as the remedy; in the latter the potassa fusa. And if, in the use of these means, proper care and caution be observed, they will, I believe, never fail. Moreover, they would be applicable to the greater number of cases that occur, if employed at a sufficiently early period, inasmuch as, as has been stated before, a very large majority of nævi

are, at the time of birth, very small. I have, however, from the want of proper care and caution in the use of these means, seen much mischief ensue. I have observed the skin destroyed far beyond what was the intention of the operator; so that, after the cure of the disease, a cicatrix remained, so large as to constitute of itself a degree of deformity greater almost than the original disease.

It is hardly possible to keep an infant quiet while any thing is done to it which occasions pain. I therefore, before making use of either the potash or acid, always apply a thick coat of sealing wax varnish to the parts surrounding the nævus. By this simple contrivance I am able to confine the action of the caustic to the necessity of the case, and at the same time to operate with greater freedom. To some surgeons who are not much in the habit of using the stronger caustics, it may appear that I am recommending an unnecessary precaution; but I feel pretty confident that if they make trials with and without it, they will readily admit the advantage of my plan. A single application of the potash is sometimes sufficient, especially if it be used in the form of paste, as recommended by Mr. Abernethy for the making of issues; but it is generally necessary to repeat the acid several times. I have found that it is generally better to prevent suppuration, if possible, in which case the destroyed part will be thrown off as a scab, and the consequent scar will be less. This can in most cases be accomplished by keeping the part exposed, and occasionally wetting it with a spirituous lotion, containing also mucilage of acacia and oxide of zinc.

I have cured between two and three dozen nævi by these means; but it would be unnecessarily occupying the time of the reader to detail any of them, as it would be little more than repeating the description of the plan which I have been just giving.

The caustic potash has been so strongly recommended by Mr. Wardrop, and the nitric acid has been so long employed by different practitioners, that I claim no merit for adding my testimony in their favour. My only object in noticing them has been to suggest a more judicious and a safer mode of using them, and to recommend their employ-

ment at the first moment after birth that a nævus is observed to be increasing.

I should have stated, that the cutaneous portion of a nævus will sometimes, though rarely, remain after its subcutaneous parts have entirely disappeared. In that case I apply to it concentrated nitric acid, or the caustic potash, by which means every vestige of the disease is readily and easily removed: indeed, I believe whenever the cutaneous portion is large, this would be the better practice, as the skin which is the seat of a nævus not being of its natural texture, will never, of course, have quite its natural appearance: it will appear thinner than healthy skin, shrivelled, and more loosely attached. The scar left, too, after the healing of the wound occasioned by the caustic, if properly employed, is never so large as the original mark.

ON THE FUNCTIONS OF THE MUSCLES AND NERVES OF THE EYE-BALL.

To the Editor of the Medical Gazette.

SIR,

IN the MEDICAL GAZETTE of September 24th, will be found a communication from my colleague, Mr. Walker, of Manchester, on the Functions of the Muscles and Nerves of the Eye-Ball; in reference to which I have considered it my duty to trouble you with the following remarks. A paper by Mr. Walker, containing similar views to those published in the GAZETTE, was read at the last meeting of the British Association, held at Bristol. After Mr. Walker had sent this paper to Bristol, he read a copy of it to me; when I was much surprised to find that the explanation given by him of the functions of the muscles and nerves of the eye-ball was, with one exception—viz. the action of the superior oblique muscle—similar to my views on this subject, communicated to Mr. Walker some years since, contained in my Introductory Lecture for 1834 (which Mr. Walker had an opportunity of deliberately perusing), and further explained in a paper read by me to the Manchester Medical Society, Novem-

ber 4th, 1835. To this may be added, that I had previously informed Mr. Walker that my views on this subject were sent for insertion in the last volume of the Transactions of the Provincial Medical and Surgical Association, but that, in consequence of being too late, the paper would not appear until the publication of the next volume. Whether Mr. Walker has made sufficient acknowledgment in his paper, of the use he has made of the discoveries of another, can only be decided when an opportunity is afforded of comparing the papers; but when the foregoing circumstances are considered, would it not have been more courteous in him to have reserved his observations until after the publication of his colleague's remarks on the same subject?

I am, sir,
Yours respectfully,
R. T. HUNT.

Manchester, Sept. 26, 1836.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

De la Prostitution de la Ville de Paris, considérée sous le Rapport de l'Hygiène publique, de la Morale, et de l'Administration. Par A. J. B. PARENT-DUCHATELET, Membre du Conseil de Salubrité, Médecin de l'Hôpital de la Pitié, &c. Deux Tomes. Baillière.

THIS is one of the most remarkable books we have met with of late. It abounds with information of a singular kind, interesting at once to the physiologist, the moralist, and the medical statistician. The labour which it cost the author must have been immense: he was engaged upon it for several years, and after all, unfortunately, did not survive to see it laid before the public. Parent-Duchatelet died in March last, at the comparatively early age of 45, exhausted by the toils of incessant research.

As we intend to bring this work on more than one occasion before the reader, we shall limit ourselves for the present to a brief notice of its contents.

The chapters of the first volume commence with generalities respecting the number of prostitutes in Paris, the parts of France from which they generally come, the families they usually spring from, and the causes leading to their ruin. The characteristic manners and habits of these unhappy females are then treated of: after which we have a sketch of their chief peculiarities, taken in a physiological point of view. The several arrangements of medical police and *hygiène* adopted with regard to the *prostituées* in Paris, are noticed at much length; and we are next presented with such a picture of the mode in which the various *maisons* in that regularly-profligate capital are managed, as we might expect from the author had he been assisted in his explorations by another *Diable boiteux*.

An ample account is given in the second volume of the sanitary regulations observed with respect to the *filles publiques*; the hospitals for the treatment of syphilis are described; and the houses of correction, with the several methods of punishment followed in each, are afterwards noticed. Certain details of a curious nature, but most important in relation to state-measures and administrative policy, form the conclusion of the work.

The whole is said to be founded on documents the most authentic, procured, in fact, in the government offices of France; and no pains seem to have been spared by the author to supply, by actual observation and personal inquiry, all the knowledge which in that way could be obtained for the completion of his extraordinary undertaking.

A very striking peculiarity of the work is the propriety and decency with which every question is discussed: we believe that notwithstanding the delicate nature of very many of the subjects touched on, there is not the least impurity in the author's mode of handling them; his language, though free and unfettered, contains no expression calculated to give offence to modesty or good taste.

Among the points noticed in the physiological portion of the work are, the *embonpoint* of most of the *prostituées*, the peculiar voice which many of them have, their infecundity, their stature, the prevailing colour of their

eyes and hair, &c. It might at first seem that it were impossible to avoid fanciful speculation in treating of such matters, but, on turning to the chapters referred to, we find that all rests on observation and the official returns.

MEDICAL GAZETTE.

Saturday, October 1, 1836.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

FACTS VERSUS FALLACIES:

BEING A FEW HINTS TO STUDENTS ON THE
OPENING OF THE SESSION.

OF all the qualities which the student needs to possess, who visits the metropolis with a view of pursuing his professional education, there is none that he will find more requisite, even at the very first step, than caution. He should know that there are those abroad who lie in wait for his credulity, and that he must be particularly on his guard against volunteer guides. We feel obliged to give this hint, *in limine*, on observing the recent conduct of our dishonest contemporary — the Lancet. With this brief admonition to our young friends—to be cautious under whose guidance they place themselves—we dispense with giving further *advice*: in the remarks which follow, we appeal to their reason and understanding.

There are two signs by which the dishonest proceedings of the party in question may be discovered and unmasked—first, the gross partiality with which he cries up a certain set of teachers; and secondly, the falsehoods and lying statements with which he endeavours to carry on his work of deception.

As to the first, it is *so* gross, that none but the most simple and inexpe-

rienced can be deceived. The trick is perfectly well understood about town, and is only adapted to catch the novices who are very fresh and green from the country. To so shameless and brazen a pitch is the system now carried, that all the walls in the neighbourhood of London might as well be chalked with the emphatic puffing of — TRY WAKLEY'S MATCHLESS. But the *honourable* member for Finsbury has always some such respectable scheme on his hands, and is now only doing that for the Gower-street speculation which he lately used to do for that bantling of his in Lancaster Place. His COLLEGIUM WAKLEYANUM has been wholly exploded, or abandoned of late, to make way for his new favourites of "University College."

All this is so palpable and notorious, as not to require dwelling upon. But the systematic attempt of the Lancet to mislead the young men who arrive in London about this season, and to injure all the other medical schools of the metropolis, to the teachers in which he is personally hostile, is so replete with falsehoods and wilful misrepresentation, as to require a special exposure. The last number of the journal just named contains what the Editor is pleased to call a "résumé of admonitory comments;" in referring to which he says—

"Neither there nor in this place, however, shall we attempt to institute any comparison into the respective merits of the various establishments or teachers. The invidious nature of such an undertaking—the task which such an investigation must impose—would require nerves of iron for its execution, with strict impartiality; and, at last, great injustice might be done,"—*et cetera, et cetera, et cetera*.

After this declaration of the undertaking being "invidious," and of there being a risk of doing "great injustice," we felt confident that the "comparison"

was to be made, and some mystification attempted: nor were we deceived; for at page 19 the mask is thrown aside, and as pretty a specimen presented to us of adulation of one party, and misrepresentation of others, as any one could desire to see.

The object is to represent the school of University College, Gower Street, as by far the cheapest in London; and the mode of effecting this, is by taking the North London Hospital, and setting it in the foreground of the school to which it belongs. Now if all that a pupil had to do in London were to attend an hospital, this would be very fair; but as it happens that he has certain lectures to attend also, it is quite clear that the only honest and rational method of calculating the comparative expenses of different schools, is to take the amount of fees *for the lectures and hospital attendance together*. If this be done, the account will stand very differently from that into a belief of which our dishonest contemporary endeavours to betray the pupils.

At once the simplest and most generally applicable comparison between the different schools is, to ascertain for what sum at each the pupil may attend, during an unlimited period, all the lectures required by the College of Surgeons and Society of Apothecaries. The calculation stands thus:—

	£	s.
Aldersgate School	46	4
Webb Street	52	10
Westminster School	52	10
Middlesex Hospital	53	11
St. Thomas's Hospital	55	13
St. George's Hospital	56	14
King's College	63	0
London Hospital	63	0
St. Bartholomew's Hospital ..	65	2
Guy's Hospital	66	3
University College	74	10

[For farther details, see the table which follows the present article.]

This requires no comment: as regards lectures, the University College is the most expensive school in the metropolis,

whether for the shortest attendance required by the corporate bodies, or for an unlimited period; for the latter, the difference between it and some of the best private schools is nearly thirty pounds, while for the former it exceeds that sum.

Now let us inquire into the facts connected with hospital attendance, and here we admit *in limine*, that a *certificate* of having attended the medical and surgical practice at the “North London” may be procured on terms—such as we trust will never be the case at any other hospital in the metropolis. Let us explain.

When young gentlemen come to London they have enough to do, Heaven knows; one lecture following after another from morning to night in such rapid succession, as necessarily to leave but a very short space in the forenoon, during which even the most zealous can be in the wards of their hospital. Heretofore no pretence was ever made of attending both the medical and surgical practice at the same time; and at the other hospitals the regulation of attending each separately still prevails. But the conductors of the North London Hospital do, what we cannot venture to designate as it deserves: they give certificates of one year's attendance on *both the medical and surgical practice together*! at the expiration of twelve months after the payment of 21*l.* into the hands of their treasurer. Long may the North London Hospital stand alone in this respect, and may its conductors find consolation in the praises of the *Lancet* for this adoption of the “certificate system!”

Considering the smallness of its size, and the necessarily very limited field of observation it affords, we have no doubt the North London is a very good hospital; but he who says “it stands forward from the rest in bold and brilliant relief,” knows nothing about the

where of which he so confidently speaks: for it so happens that he has been misled from some, and has not the nerve to say; a circumstance which it is just possible may somewhat justify his opinion.

But for the most common hospital attendance now adopted by pupils, is one year of the medical (which frees them for eighteen months), and one of the surgical practice—this qualifying for their examinations. Assuming the above as an average, we now return to our comparison of expenses. If the pupil takes his ticket at the North London Hospital for the medical and surgical practice separately, the sum is 16*l.* 15*s.* each—making 31*l.* 10*s.*; but we shall suppose that he takes out both at once, in such manner as to enable him to attend during two successive years—and for this he pays 26*l.* 5*s.*

The *Lancet*, for its own purposes, has chosen to institute an especial comparison between its favoured institution and those others—never mentioned without some misrepresentation—viz. St. Bartholomew's, Guy's, and St. George's. We shall take the same, and in the same order. The paragraph is not very intelligible—indeed, is scarcely English; but we shall quote it verbatim, to show the extent of the deception which it is attempted to practise:—

“But suppose we compare the 26*l.* 5*s.*, charged at the North London Hospital, with the sums charged at the other hospitals for attendance to pupils who are not dressers. The charge, even then (the attendance, also, on the surgical practice being limited to twelve months) will be more than 30*l.* higher at St. Bartholomew's (for instance) and more than 24*l.* higher at Guy's Hospital (as another instance), and more than 51*l.* higher at St. George's, (perpetual there to both) than the charge at the North London Hospital.”

Now, instead of following this calculation, which we submit is nearly unintelligible, we shall compare things which

are similar, and which will afford useful information. We suppose that, as is usually done, the student wishes to attend the medical and surgical practice for the periods required by the College of Surgeons and Society of Apothecaries respectively—viz. eighteen months and one year. At St. Bartholomew's a pupil may attend the medical practice for a year and a half, and the surgical practice for ever, for 42*l.* But this sum, instead of being “more than 30*l.*,” is only fifteen guineas above what he would pay at the North London hospital, containing only one-fourth the number of beds. At Guy's, the fee is within one shilling of being the same as at St. Bartholomew's, while the pupil has the advantage of attending also the surgical practice at St. Thomas's.

Come we now to St. George's; and here we particularly solicit the attention of the reader, because, when it is mentioned by our contemporary, a more impudent fabrication than usual is always sure to follow. It is intended to convey the idea, not only that St. George's is enormously dearer than the North London, but that it is even more expensive than St. Bartholomew's or the Borough hospitals. Now the fact is, that a pupil may attend the surgical practice of St. George's Hospital, for a year, for 21*l.*, and the medical practice, during eighteen months, for 16*l.* 16*s.*; or, if he take the medical ticket first, he may then attend the surgical practice for four guineas less; being, in all, 33*l.* 12*s.* But it would cost him 26*l.* 5*s.* at the North London hospital; so that the difference for the attendance required by the College of Surgeons and Society of Apothecaries, is only seven guineas!!!—and setting aside the great disparity in the size of the hospitals, the St. George's surgical pupil has the privilege included of acting as a dresser for three months.

Again: taking a general view of all the expenses, we find that the sum required

for attending the lectures, and the hospital practice required by the College of Surgeons and the Society of Apothecaries, at St. Bartholomew's, amounts to 107*l.* 2*s.*; at Guy's, to 108*l.* 4*s.*; at St. George's, to 90*l.* 6*s.*; at University College, to 100*l.* 15*s.* So that the whole expense at the magnificent establishment of Guy's, and including the practice of two great hospitals, exceeds the North London Hospital School, and its hundred beds, by only 7*l.* 9*s.*, and at St. Bartholomew's, only by 6*l.* 7*s.*, while at St. George's Hospital the expense, instead of being greater, is less, by 10*l.* 9*s.*

So much for the veracity and fair dealing of our advocate for Gower Street and its hospital. A word more, and we have done.

If we turn for a moment from his exertions in favour of that establishment, to the men connected with it, or the man rather, who forms the special subject of his laudation, we must acknowledge at least the gratitude of the worthy editor, however we may wonder at his consistency and discrimination. Mr. Liston, the present idol of Wakley's attachment, is, we believe, the only person of any standing in the profession in London, who is desirous of the good opinion of the honourable member for Finsbury; he has not been ashamed to be present at, and to take part in, meetings where Wakley has been prominent: hence, naturally, the reciprocal feeling on the part of the latter. The great attraction now at the North London Hospital is Mr. Liston: Mr. Liston is all in all, just as it used to be with Dr. Elliotson, who at present seems to be completely thrown overboard. Why is this? Not one little word even of passing courtesy is expended on the Doctor, who could once boast the warmest support of the worthy Finsburian. How are we to account for this phenomenon? Are we right in

attributing it to the mortal hatred that subsists between Dr. Elliotson and the *great surgeon* of the North? We doubt not we have hit the mark, as the participation of feuds and faucies is one of the signs of firm and steady friendship: the *idem velle* and *idem nolle* is here complete; and long may it subsist in its beautiful harmony and concord!

A word, however, on the consistency of the thing. Mr. Liston is held up as the model of surgeons — the greatest after Sir Astley Cooper, and so forth. How is this, when we have Mr. Lawrence still amongst us in all his pristine vigour and ability, who was once vested with the championship by the same discriminating judge, nor was stript of it, that we are aware, for any deficiency or inferiority of skill? But Mr. Lawrence shook off the patronage of Wakley, and hence the rival that has been set beside his throne.

But Mr. Wardrop, poor man! what has *he* done to merit this unceremonious set down from the post of honour? Has he no means of *intercepting* the favours which are now so thickly bestowed on his brother surgeon? Or are his *intercepted* favours exhausted, and his means of paying due homage to his patron extinct? Whatever be the cause, it is clear that the once celebrated Mr. Wardrop is no longer a star in the ascendant, and that, though he would want some little support in resuming his difficult task of lecturing again in an obscure quarter, he can no longer reckon on more than a little "faint praise" from his quondam panegyrist!

Be warned in time, all ye who aspire to the good opinion and the graces of our respectable contemporary. Let the things that have been be a warning to you; and wait but a little, we advise you, to observe the career of the present protégé of the North London Hospital.

[Table, &c.

TABLE,

Shewing the amount of Fees at the different Schools, for attendance on the Lectures required by the College of Surgeons, and Society of Apothecaries.

	Anatomy and Demonstra- tions.	Medicine.	Surgery.	Chemistry.	Materia Me- dica.	Midwifery.	Botany.	Forensic Me- dicine.	Additional percentages on those who have not a numeration.	Matriculation Fee.	Total.

* In the Prospectus of the University no terms are mentioned except for one Course,—viz. £15 10s.; we presume we do not overrate the perpetual ticket in making it £4.
N.B. At several of the schools, as the Aldersgate, London Hospital, &c., a general fee is taken, at a considerable reduction.

REMARKS

ON THE

PRESENT STATE OF IRISH
MEDICAL CHARITIES.*To the Editor of the Medical Gazette.*

SIR,

THE late Report of Dr. Borrett on the state of the medical charities of Ireland, published in the pages of your valued journal, must be viewed by English practitioners with surprise and astonishment. The existence of such a state of medical affairs has now been incontrovertibly established, and with a greater degree of weight and confidence than could be attached to the report of any local practitioner, the value of which, as prefatory to a more extensive investigation of the subject, is too obvious to require my dwelling on. Abuses the most extensive, negligence the most culpable, have been clearly proved; and I trust on a more general review of the subject, to a portion of which it is possible Dr. Borrett's ambulatory commission did not extend, to demonstrate as clearly, that professional treatment, inferior to that of the darkest ages, or medico chirurgery in its earliest infancy ever produced, is daily practised at our dispensaries, an epitome of which I think indispensably necessary to a just appreciation of, and a more intimate acquaintance with, the inutility and really injurious operation of those charities, although apprehensive, in this age of professional attainment, it might be viewed as the creation of fancy.

If an opinion relative to the civilization of Ireland, and its degraded position in the scale of social existence (as advanced in a learned editorial article in a late number of the *MEDICAL GAZETTE*), is to be based on the state of her medical charities, the estimate, without any great stretch of privilege, must be extended to parties who, as members of an enlightened, a learned profession, support but indifferently enough its character for respectability or learning; for, after a most extensive and intimate survey of the state of our dispensaries, I am firmly convinced their debased state cannot be attributed to the condition of the applicants, or solely to the careless indifference of the managers, but is to be chiefly imputed to the physicians and surgeons of those establishments, who could in a very considerable degree, if not altogether, counteract the negligence and supineness of the moral governors, were they to rouse themselves

from that state of apathy and indifference to the comforts and healthful existence of the people committed to their charge, that so suddenly and incorrigibly usurps the place of an ephemeral zeal, which scarcely forced them through a hurried and imperfect education. Were they lovers or cultivators of science, and acquainted with medicine and surgery in their present advanced state, they could never hope to combat disease without the aid of those valuable medicines whose character practical experience has long since established, or those active remedies which modern discoveries have placed at our disposal. But slaves to a wretched empiricism, and prepossessed with a fatal but convenient faith in the powers of a single medicine, or two at most, being sufficient for the radical cure of every disease, they slumber in unlettered ease, satisfied with, nay, conceiving more than sufficient, that knowledge hastily acquired during a few winter seasons of metropolitan residence. This is sufficiently evident from the paucity, the unvariedness, and vile description of the medicines usually found in those hovels, which are so badly calculated to afford relief to the unfortunate applicants; some of whom, being a certain description, of farmers recommended by their landlords, or any other subscriber, are not altogether uneducated, who, to a person familiar or intimately acquainted with their habits, manners, and dispositions, which cannot be acquired without a residence amongst them, appear shrewd, intelligent, and discriminating, appearing quite as conversant with ordinary acquirements and newspaper intelligence as their superiors. This description equally applies to the tradespeople, and extends, with some limitation, even to day-labourers, all of whom occasionally become the subjects of dispensary relief, are living on terms of most intimate intercourse and familiarity, discussing medical affairs when grouped around their firesides as freely as politics, drawing their conclusions after their own peculiar fashion, but, of a truth, seldom erroneously; canvassing the merits and demerits of the dispensary doctor and his practice with as great a degree of freedom and warmth as those of the Prime Minister, and, if worthy of such feeling, bestowing on him all that sincere and ardent affection so characteristic of the Irishman.

When illness invades the habitation of one of those people, or the member of a family becomes the subject of accidental and severe injury, recourse is immediately had to his own resources or those of his friends, and a variety of domestic remedies indigenous to the country, or pro-

cured at a sufficiently low rate from the shop of an apothecary in some neighbouring town—medicines usually had recourse to on the invasion of every disease—are freely administered, as it may suit the wish of the sufferer, or accord with the views of some old crone pretending to superior and mysterious skill in those matters, but, as often happens, without success. Long-continued disease, and consequent loss of employment, involve the unhappy sufferer, and perhaps a numerous family, in unparalleled and hopeless destitution. Now the victim of despair, application is made to the local dispensary; but what relief can be afforded from its resources? None. The patient submits to a repetition of drenching with a sarrago of rotten trash, remedies superior to which he has already used, and places reliance on advice equally rotten, musty, and infellectual—advice emanating from the head of some Esculapius, whose intellect, from a long oblivion of medico-chirurgical matters, and a diligent pursuit of other objects, has been rendered rusty and threadbare. Professional incapacity, as usual, ends in failure of success; and this so very frequently occurring, begets a distrust and want of confidence on the part of the applicants in our dispensaries, which fully accounts for the infrequency of attendance on advertised days, mentioned in Dr. Borrett's report. Numbers of those fancied incurables might be daily seen migrating to the habitations of other distant practitioners, whose more successful practice and superior attainments have established for them a respectable reputation, most of those invalids returning restored to health, and rendered useful members, if not to society at large, at least to their own immediate friends.

I have known numerous instances where those people walked one hundred miles for relief, and successfully, submitting to operations with a heroism instigated alone through a determination to rid themselves of disease at all hazards—diseases not comprehended, and operations which could not be performed, at the district dispensary. Even while the writer was penning this article, a young man was brought to him from a distance of thirty miles with fracture of the humerus, extending into the elbow-joint, passing during his journey through a country containing six dispensaries; and when inquiry was instituted of his father why he did not seek assistance at one of those institutions, he unhesitatingly declared he considered the injury of too serious a nature to commit to the management of a dispensary doctor.

Such are the impressions on the minds of the people, such their faith in the relief

and assistance afforded at our medical charities, where they witness disease, except of the most ordinary nature, allowed to commit unrestrained its destructive ravages; indeed, with such evidences before them, any other feeling would portray an obtuseness of intellect which does not form a feature in our national character. What more successful result could be anticipated, when the medical attendant, viewing his dispensary appointment as a snug sinecure, an unalienable property, spends his days without restraint, indulging in the allurements of the Irish chase; and a prince of good fellows, devoting his nights to potations of the native, enlivening the festive board, or delighting the members of a union hunt with the variety and melody of his songs, and shallowness of his wit; loudly expatiating on the properties of the Irish fox hound, depicting the beauties of a previous chase, and describing the various incidents of superior jockeyism and hairbreadth escapes during their last run, from the moment reynard first breaks cover, to the death, with a delight and vividness of description, that proves this to be his dearest, his all-absorbing study.

A devotion to such pursuits must alienate their minds from a close attention to the arduous duties of a profession; and the more usual result is, for those gentlemen still holding their dispensary appointments, to settle themselves in life as farmers—to be seen from morning to night directing the movements of the plough, or as amateur cattle feeders, horse jobbers, and road makers, to be seen at every country fair anxiously learning the prices of swine and black cattle, attending with punctuality every turnpike meeting, and, with an ill-timed zeal, aping the ostensible public character at the sacrifice of the professional, to the no small amusement of the country gentry, who are unavoidably driven to the conclusion that his skill and taste lie more in the Macadamizing some public highway than in the practice of medicine.

To dwell much longer on this subject, would be, I fear, to trespass on your indulgence, and the patience of your readers, the field for investigation being a most extensive one: were I to treat of the management, or rather mismanagement, of every local dispensary, it would afford matter for a report too voluminous, as a single article, for the pages of your very valuable journal. And as the medical management of the Infirmary of Cork has received a well-merited eulogium in the report of Dr. Borrett, to which the writer can bear ample testimony, the medical officers of those establishments being gentlemen of

respectability and acquirements, leaving them and the charities whose destinies they wield, to enjoy the honours of a well-earned and richly-merited reputation, I shall, for the present, as a melancholy contrast, direct your attention to the abject state of an unfortunate and fallen brother, as a view of its medical operations will elucidate what must be the state of those charities in more retired districts, and enable your readers to appreciate the subject with greater clearness and justice. I am now about to bring under review an hospital (not a county hospital) combining in one establishment a dispensary, fever hospital, with a wing of the building set apart more especially for surgical cases, altogether well calculated, from its architectural arrangements, to meet the object for which it was destined, and, under better auspices, might be rendered a valuable establishment, spreading its sanative influence over a wide extent of country, and conferring blessings which would prove incalculable; but withering under the deleterious influence of a blind and besotted party spirit, which, ever reckless of evil consequences when goaded by the ungenerous desire of supporting some favoured object, in open violation of the claims, the calls of humanity, in this instance, benumbs the feelings of all parties to the sacred duty imposed on them, of rendering the hospital committed to their trust extensively useful to the suffering applicants, and causes them to rest satisfied that every thing connected with the establishment should savour of indolent inactivity, and to permit those funds committed to their charge—funds more than sufficient to meet every exigency, and for one of the most sacred purposes—to be frittered away without credit to the establishment, or benefit to the public. The financial arrangements of such an hospital are much to be deprecated; but when, to perfect the picture of ruin, professional incapacity must be added, an accumulation of evil is heterogeneously amassed, the extensively felt, and destructive effects of which, must be apparent to every individual. Here all is empty parade, and within its walls the usual empirical routine of treatment is adopted, in short, being a soil congenial to the growth of the principle of infallibility: in one or two remedies, every disease incident to human nature is encountered with the same all-powerful drench, quantities of which, from an old crock, are daily ladled out to the various applicants, with bowels already too much relaxed from a diet of potatoes, sour milk, and salt fish, or from a too free use of some domestic purge, previous to application: is it to be wondered that patients indiscriminately sub-

jected to such a regimen, without any appreciable benefit, should fly from the diabolical mixture, as they call it, to seek that relief from the house of some private practitioner, which the believer in one universal remedy was unable to afford? The natural result is a disinclination on the part of the people, except in cases of the most urgent and extreme necessity, to apply for relief, or enter the wards of such an hospital; and when unavoidably forced to become interns, a want of confidence and distrust on the part of the patients in the medical attendant exists, but little calculated to afford relief to one party, or satisfaction to the other, every circumstance concurring most effectually to frustrate the benevolent intentions of the charity. The medical treatment of this hospital must be too apparent, from the general tenor of this paper. Of its surgical arrangements I shall give but a brief sketch, in which I have to present the subjects of simple fracture of the middle third of the thigh, as recovering with considerable shortening and a bowed state of the limb, causing a deformity which renders the unhappy sufferer ever afterwards a cripple; fracture of the fibula, recovering with a lameness, and evil consequences resulting from the maltreatment of such an accident; fracture of the clavicle, treated with a pad placed on the prominent end of the fractured bone, and the other arrangements quite in keeping with such erroneous views; dislocation of the lower head of the tibia forward, undetected, or at least no attempt made at reduction, and the injury left to the unaided operations of nature; disease of the eye, very prevalent amongst the poor, totally neglected and misunderstood, left to run its fearful course unchecked, and to terminate with most melancholy and wretched results; the operations of surgery never performed, and those whose diseases require operation left to pine in suffering or seek assistance as chance might direct, or the reports of some distant and more gifted practitioner might attract them. Such is an epitome of the practice of an hospital in the South-West of Ireland; and blush, oh, ye monopolizing guardians of Irish surgery, who uphold the principle that all appointments of trust and consideration are to be committed to your safe keeping, to the exclusion of all other surgeons, that such practice could emanate from one of your boasted Licentiates; and turn with disgust from the page, as I do from the subject, that in this age of professional advancement such practice could emanate from the veriest tyro. During this posture of affairs, I fear the endeavour to reform the Irish medical charities will prove a Herculean labour. However, as the spirit of

reform is beginning to dawn on us, we anxiously look forward to the result of the late investigations as leading to that reform which is so imperatively called for; some such measure having been long and severely felt as indispensable to the establishing our Irish Dispensaries on a more respectable and useful footing.

HIBERNUS.*

Co. Cork, Sept. 19, 1836.

ORIGIN OF THE LATE CAMBERWELL MEETING.

LETTER FROM MR. CRISP.

To the Editor of the Medical Gazette.

SIR,

FOR many reasons I feel reluctant to enter into a correspondence with Mr. J. F. Hulbert; but I am compelled to reply to the misstatements contained in his letter, published in your last number, and I cannot better refute his assertions and insinuations than by giving a brief account of the origin of the meeting which took place at Camberwell; and it is as follows:—

The Poor-Law Commissioners recommended the Governors and Guardians of the poor of Camberwell (Peckham and Dulwich are both in this parish) to abolish the parochial surgeons, and form a medical club in their stead. The said Governors and Guardians (without first consulting the medical men) framed a set of rules, and sent them to all the practitioners in the parish. In this prospectus it is stated, "that the poor will have the satisfaction of feeling that they will no longer be supported by *charity* [a blank space is left for donations and subscriptions], either in sickness or in health, and they will *then become independent*. All domestic ~~servants~~ whose wages do not exceed 12*l.* are to be physicked for 4*s.* per ~~annum~~. A mechanic receiving 35*s.* per week, to pay for himself and wife, 5*s.* yearly. A single man, earning 25*s.* per week, 4*s.* &c. &c. &c. The medical attendant to find medicines. No person whose wages exceed the above shall become a member, except consent in writing be expressly given by the managing Committee." [This Committee is composed solely of eight clergymen.]

A few gentlemen, the greater number of whom, I have since learnt, acted without at all considering the matter, sent in their names as supporters of the scheme (*conditionally*, however).

The Governors and Guardians next in-

vited the medical practitioners of the district to meet them at the Poor House (September 7th); but the former, thinking that the affair principally concerned themselves, retired into an adjoining room, and, after discussing the subject, it was agreed that the meeting should be adjourned till the following Tuesday, when the medical men residing in the Camberwell district and its *neighbourhood* should be invited; and a note to this effect was given, by Mr. Bristowe, the chairman, to Mr. Manico, the secretary: but, by some *unaccountable* accident, the word *neighbourhood* was omitted. Before these circulars were sent out, I had been invited; and as I heard that it was the wish of all present at the late meeting that the practitioners in the *neighbourhood* should attend, I mentioned the circumstance to a few friends, and also to Mr. Waterworth (who, on a late occasion, took the chair at Mr. Hulbert's house), whom I knew to be favourable to the plan, and requested him to make it known to the gentlemen whose opinions coincided with his own.

And now, sir, on referring to the list, it will be found that twenty one of the gentlemen *are residing in the Camberwell district*; and I may add that *all* the dissentients spoke on the occasion alluded to, but only seven of the majority expressed their opinions: it is true that the former said but little, but I presume that they brought forward every argument they could adduce in support of their cause.

I have, sir, in conclusion, to complain of Mr. Hulbert's somewhat invidious mode of writing. I wish he would be *personal* enough to state names, and I dare assert that the gentlemen who descended to personalities ~~are prepared to justify themselves~~ for so doing, and to prove the correctness of every statement they made.

I am, sir,

Yours respectfully,

E. CRISP.

Walworth, Sept. 27, 1836.

(Prospectus.)

CAMBERWELL INDEPENDENT MEDICAL CLUB.

STEWARDS.

The Rev. John George Storie, Vicar of the parish; Rev. H. Melvill; Rev. H. W. C. Hyde; Rev. S. Smith; Rev. E. Lilley; Rev. M. Anderson; J. T. Allen, Esq.; L. B. Allen, Esq.; C. Baldwin, Esq.; Mr. S. Beale; J. Brett, Esq.; T. B. Burbridge, Esq.; J. Capes, Esq.; Mr. J. Deacon; C. Dodd, Esq.; R. A. Gray, Esq.; C. Harden, Esq.; R. Hichens, Esq.; W. Hichens, Esq.; Mr. G. Marshall; A. Nairne, Esq.; J. Pew, Esq., R. Pope,

* We have altered the signature for a reason which our correspondent will understand.—E. G.

Esq.; S. Pope, Esq.; E. Puckle, Esq.; S. Richardson, Esq.; R. Thomas, Esq.; J. Williamson, Esq.

Treasurer, — Honorary Secretary, — Collector, Mr. T. Prebble, 13, Southampton street.

The attention of the working and labouring classes is called to the formation of a medical club in this parish—the objects of which are, that all the poor families may have medical and surgical attendance and medicine during sickness, without recourse to parochial aid. The poorer classes, who are invited to belong to this club, will have the satisfaction of feeling that they will be no longer supported by *charity*, either in sickness or health, and will then become *independent*.

It is intended to discontinue the attendance of the present parochial medical officers, as regards the parish engagement, and no medical relief after 25th March next will be afforded out of the workhouse; it is therefore deemed advisable to form the club immediately, that it may come into full operation at *Lady-day* next. The principle upon which the club is founded, is, that all the labourers should belong to it, and each will have annually to subscribe according to family, as under-mentioned—the payments to be made half-yearly.

The following medical gentlemen have consented to attend the members and their families when ill, viz.:— * * *

The inhabitants generally are reminded that the formation of this club will save the parish several hundred pounds per annum, besides having the effect of restoring to the English peasantry a feeling of independence, and creating a proper dread and dislike, as well of a parish workhouse, as parochial relief.

RULES OF THE CLUB.

I. The members shall consist of labourers and servants in agriculture, or in handicrafts and trades, both male and female, strictly belonging to the working classes. But no domestic servant receiving more than *twelve pounds* annual wages, nor any artizan, handicraftsman, or other workman, receiving more than *one pound five shillings* per week wages, or whose earnings, together with those of his children under sixteen years of age, exceed *thirty-five shillings* per week, shall be permitted to be a member of this club, except consent in writing shall be expressly given by the stewards.

II. Each member, on admission, shall pay six months' subscription in advance, and shall then be entitled to the benefit of the club; and the same amount shall be paid half-yearly in advance, at *Lady-day* and *Michaelmas*; and the accounts of the

club shall be annually balanced at *Christmas*.

III. Members may be admitted at any time, on paying the full subscription for the current six months in advance: the next payment becoming due at the ensuing *Lady-day* or *Michaelmas*, as the case may be.

IV. Every individual without a child, shall pay annually, 4s.; every widow or widower with one child, 5s.; every man and wife, 5s.; every man and wife with one child, 6s.; every man and wife with three children, 8s.; every man and wife with four children, 9s.; every man and wife with five children, 10s.; and be entitled to receive all requisite advice and medicine from such one of the medical attendants as the member may select.

V. The children of members above sixteen years of age (unless they be idiots or helpless cripples) shall not be included in the subscription of the family, but must pay for themselves as independent members.

VI. The wife of a member may be attended during her confinement, on paying to the Collector of the Club ten shillings one month before the time at which she expects to be confined; and may select her own medical attendant from the gentlemen before named.

VII. A man and his wife may be permitted to subscribe for themselves alone, but not for their children alone, nor for any child separately; if they subscribe for any one child under sixteen years of age, they shall subscribe for all their children under sixteen who may reside under their roof, according to Rule IV.

VIII. Any member may be permitted to subscribe for his aged and infirm parent or parents (if unable to support themselves, and residing with their son's or daughter's family) on the terms prescribed for a man and his wife and children under sixteen; that is, counting the parents as children.

IX. No candidate who is actually ill, or any one of whose family is ill at the time of his or her application, shall be admitted a member, unless he or she procure two healthy persons to enter at the same time, each paying the current half year's subscription in advance; or unless he or she pay such admission fee as the medical attendant shall deem an adequate consideration for the attendance and medicine which such candidate, or any part of his or her family, may require in his, her, or their *then* illness. After admission on such terms, the annual payments shall be the same as those required for other members of the Club.

X. Each member shall on entrance, and also at the time of paying his subscription, name the medical gentleman by whom he

wishes to be attended for the ensuing half year, and no member shall be at liberty to change his medical attendant, except at such time.

XI. Sick members shall furnish their own bottles and bandages; and when able shall attend on the medical man, who will visit them at their own houses when they are unable so to attend.

XII. Habitual drunkards, and persons notoriously addicted to profligate habits, or who are known to be idle and disorderly, and individuals convicted of felony, shall not be admitted members of the Club, or if admitted, shall not be allowed to continue members.

XIII. Every dispute or disagreement which may arise shall be referred for arbitration to the stewards, and their decision thereon shall be final.

XIV. The name, age, and residence of each member, shall, on admission, be entered in a book by the collector, with the name of the medical attendant whom the member may then select, and this registration shall be renewed every six months, when the member pays his subscription.

XV. All subscriptions shall be paid to the collector on the days named in Rule II.; and if any member shall fail to pay his or her subscription for the space of *one fortnight* after either of such days, he or she shall cease to be a member; and no member whose subscription is in arrear shall be entitled to receive medical aid from the Club.

Any person thus disqualified, may, at the discretion of the stewards, be permitted to renew his subscription, and to become a member, on payment of a fine of one shilling, and conforming to the Rules II. and III.

XVI. The subscriptions of members shall be paid over by the collector to the treasurer as they are received, and the stewards will settle with the medical gentleman whom the members have respectively elected to attend upon them, every six months, by paying the amount of subscriptions received under Rule IV.

WAX MODELS OF SURGICAL ANATOMY.

We have seen two very fine models, just imported by Mr. Schloss, of Great Russell Street, which we think are well deserving the notice of the profession. One represents the male pelvis, viewed laterally, shewing the urinary and genital organs, with the parts affected in inguinal and femoral hernia. The interior of this model

displays the pelvic viscera *in situ*, together with the kidney and ureter, the course of the abdominal aorta, of the common internal and external iliac vessels, with the distribution of their branches, the abdominal rings, with the spermatic vessels and vasa deferentia.

The second model presents a side view of the male pelvis, shewing the reflection of the peritoneum around the viscera. Here, also, we have an excellent representation of the descent of a large scrotal hernia, dissected and slit open, so as to display its coverings and contents.

Models of this kind must be invaluable to teachers of surgery; while, as specimens of art, they must secure the admiration of all who inspect them.

NOTICES.

Mr. May's letter is an advertisement.

"Medicus."—A letter professing to state facts should always be authenticated. By the way, the letter signed Medicus, to which our notice of last week referred, was dated from the Borough.

"A Camberwell Practitioner," too late for this number.

"T. G.'s" letter also reached us too late.

The Aylesbury "Handbill," given in a recent number, was stated, by mistake, on our wrapper, to be put forth by one of the surgeons of the Bucks Infirmary.

To several correspondents we have apologies to offer for the temporary postponement of their papers. Next week we trust to make amends.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE II.

On Medical Evidence in general—Coroners' and other Courts—Mode of Examining Witnesses—The Sitting System—Quoting Authorities—Question of Privilege—Conduct of Medical Witnesses.

BEFORE we enter on the consideration of those special questions which constitute the main business of Forensic Medicine, it may be well to dispose of certain generalities connected with the subject. From what was stated in the last lecture regarding the nature and objects of this study, it will have been gathered that one of the chief ends of medico-legal proceedings is the giving of evidence in courts of justice: it would seem, therefore, advisable, in the first place, to take a view of those relations in which the medical practitioner stands, in respect to our legal tribunals.

COURTS OF JUSTICE.

The courts of justice in which the presence of medical witnesses is most usually required, are those of a *criminal* jurisdiction—as the coroner's, and the oyer and terminer sessions,—or those for the redress of *civil* injuries—such as the common law courts, and the ecclesiastical. Of the former, or criminal kind, that which makes by far the most frequent demand on our services, is the coroner's court.

Coroner's Court.—The circumstances under which a medical man may be sum-

moned to appear in this court are either *general*—such as might lead to the attendance of any other witness, to depose, for instance, to certain matters of fact of which he may happen to be cognizant—or *special*, as when he is expected to give his professional opinion. This is likely to be understood henceforth better than it has been hitherto. Until recently there was no difference observed betwixt summoning a medical, and any other witness. The professional man, when called upon, came, of course, but he frequently exercised a discretion: he answered all ordinary questions, and acted in every respect as a common witness; but when asked his opinions, or requested to open a body, or to analyze toxicologically the contents of the stomach, he usually declined, till he was assured of a remuneration for his medico-legal services. This, however, was what the coroner had it not always in his power to give, and much unseemly squabbling was the consequence—the medical man insisting on his fee, and the coroner endeavouring to extort the witness's opinion without one. The case is now altered. A recent enactment (6 and 7 Will. IV. c. 89) secures to medical witnesses a fee of one guinea for simple attendance, and two where a *post-mortem* inspection, or a chemical analysis, is required. But the medical man must take care that he is *specially* summoned on these occasions, for an ordinary subpoena leaves him only in the condition of an ordinary witness, when he may seek in vain for his fee. The special summons runs in this form:—By virtue of this my order, you are required to appear before me and the jury, on such a day and hour, to give evidence touching the cause of death of * * *, and to make, or assist in making, a post-mortem examination of the body, with [or without] an analysis, [as the case may be] and to report thereon at the said inquest. Signed by the coroner.

There are some points connected with

the coroner and his court, to which medical men in general do not sufficiently attend. The coroner is an officer of much power and authority. He has an extensive discretion in summoning witnesses, and ample means of enforcing their attendance. He sits as a judge, and if the finding of the jury lead to ulterior proceedings, he binds over the parties who have given evidence, to be forthcoming, and to repeat their testimony at the next assizes. His court, though it frequently be not a very showy one, the jury consisting in general of persons from the humblest classes of society, is essentially of high importance. In most cases of felony, such as manslaughter and murder, the initiative is taken in this court, and the person of the party, who by the inquisition is found guilty of the crime, is secured and committed for trial.

A medical man not duly impressed with these facts, is likely to fall into a serious predicament. He is summoned, we shall suppose hastily, and attends, it may be for the first time, in such a court. He finds the jury a set of very humble individuals, assembled perhaps in an ale-house. The circumstances are any thing but imposing. He is off his guard, and gives evidence, probably, very different from what he would have given, had he attached more importance to the proceedings. In due time, another scene follows. The witness has been bound over to appear at the assizes, and has had an opportunity in the interval of deliberately forming his opinions of the case. He then appears before a very different tribunal, and is anxious, no doubt, to make a respectable figure before the bench, the bar, and the neighbouring gentry who fill the court. His examination proceeds, and he utters his sentiments with a becoming caution: he has probably forgotten or thought no more of the obscure scene of the inquest, and the evidence he gave on that occasion. But the judge is watching him; the depositions given at the inquest are before his lordship, and are narrowly compared with the present testimony of the witness. In accordance, too, with the new Prisoners' Counsel Act (6 and 7 Will. IV. c. 114), those depositions are also in the hands of the prisoner's advocate. It may well be conceived in how peculiar a situation the medical man is placed, should his second thoughts prove at variance with those hastily given in the first instance, and especially if through his means the prisoner have been thrown into gaol, perhaps for months, on a charge of which it now turns out that he is not guilty. Nor will the compunction of the medical witness be lessened by the consideration, that, had he died between the inquest and the trial,

his depositions might have led to the condemnation of the accused!

Courts of Oyer and Terminer.—By this title we are to understand those courts of commission, or assize, in which crown cases, such as treasons, felonies, and misdemeanors, are disposed of. Medical evidence is frequently required in such cases, but the professional witness has no express or special summons: he is subpoenaed, and obliged to appear, under a heavy penalty; when in court, he must "true answer give to all such questions as are put to him," nor has he any claim to remuneration for his time and trouble in attending. An act, however, was passed a few years since (7 Geo. IV. c. 64), by which witnesses for the prosecution, in all cases of felony, are entitled to their reasonable expenses: in prosecutions, also, for certain misdemeanors, the same indulgence is granted; the misdemeanors being enumerated in the 23d section,—among which we find assault with intent to commit a felony, riot, breaches of the peace, wilful and indecent exposure of the person, &c.; cases in which medical testimony is often required, but without any special privilege or immunity for the professional witness.

Courts of Common Law and Equity.—In these courts, constituted for the redress of civil injuries, the witness is differently circumstanced from what he is in criminal cases. Where a civil suit is pending, such as an action for damages, a witness need not obey the subpoena unless his reasonable expenses be previously tendered. He must be compensated for his trouble and loss of time in going to, staying at, and coming from the place where his testimony is to be given; otherwise he need not appear: or if he does come into court, he may refuse to give evidence until his reasonable demand be satisfied. His demand, however, must be very reasonable; for a *shilling* is the stated viaticum (a sum fixed at a time when money bore perhaps twenty times its present value) if the witness reside within the bills of mortality, and be summoned to give evidence within the same. Whether medical men have a right to compensation for the sacrifice of professional emolument, incurred by their absence from home, is by no means a settled point: there are some cases reported in which they have been put on the same footing as attornies, but even the attornies' right has been shaken by some still more recent decisions.

Ecclesiastical Courts.—The only other courts which I shall notice at present, are those which take cognizance of injuries of an ecclesiastical nature. Here questions relating to the validity of marriage and the grounds of divorce are enter-

tained; cases which call into requisition the evidence of medical referees perhaps more frequently than the public are aware of. Many of the circumstances submitted to the profession, in cases of this kind, would doubtless scandalize public decency. But, on the other hand, there is much to regret; it is to be feared that justice suffers; and, at all events, it cannot but be prejudicial to medico-legal science, as well as to the practice of the bar itself, that reports of some of the most remarkable cases should not in some shape be preserved. The sanctions for attendance here are similar to those used in the common law courts; but in their dealings with medical witnesses, the parties engaged in suits ecclesiastical are understood to be bounteous, as, indeed, might be expected from the suitors in a court where few, save the wealthiest, can venture to litigate.

MEDICAL EVIDENCE.

We shall now suppose the witness in due attendance, sworn in the usual manner, and prepared to tell the "whole truth." May he always do so? Does the discretion of revealing the entire truth rest with him?

The sifting system.—The freedom of a witness in an English court of justice is greatly circumscribed. He is subjected, it is true, to several processes, such as those of examination, cross examination, and re-examination, besides, most likely, being questioned by the bench and jury,—all with the express or ostensible design of eliciting the truth. But does it follow, after all, that the whole truth is elicited? To warrant such a supposition we should be satisfied that the examining parties are fully capable of appreciating the extent of knowledge of the witness, which, where the latter is a man of science, it is not always easy for them to be. That the case is often otherwise we may be readily induced to believe, from the circumstance of able witnesses sometimes feeling obliged, through conscientious motives, to submit further information to the court after all the processes of sifting them have been finished. How many men, in such a situation, would feel deterred from volunteering one word in addition to what had been wrung from them in the ordeal they had undergone!

Much has been said of the excellence of the methods adopted in our courts for obtaining evidence, and Blackstone has placed in a strong point of view the superiority of parole over written testimony. "The open examination of witnesses *vis à vis*," says the learned judge, "is much more conducive to the clearing up of truth than the private and secret examination taken down in writing before an officer, or a clerk, as in the ecclesiastical courts, and

all others that have borrowed their practice from the civil law,—where a witness may frequently depose that in private which he will be ashamed to testify in a public and solemn tribunal. There, an artful or careless scribe may make a witness speak what he never meant, by dressing up his depositions in his own forms and language; but he is here at liberty to correct and explain his meaning, if misunderstood, which he can never do after a written deposition is once taken. Besides, the occasional questions of the judge, the jury, and the counsel, propounded to the witnesses on a sudden, will sift out the truth much better than a formal set of interrogatories previously penned and settled; and the confronting of adverse witnesses is also another opportunity of obtaining a clear discovery, which can never be had upon any other method of trial. Nor is the presence of the judge, during the examination, a matter of small importance; for, besides the respect and awe with which his presence will naturally inspire the witness, he is able, by use and experience, to keep the evidence from wandering from the point in issue. In short, by this method of examination, and this only, the persons who are to decide upon the evidence have an opportunity of observing the quality, age, education, understanding, behaviour, and inclinations of the witness; in which points all persons must appear alike, when their depositions are reduced to writing, and read to the judge in the absence of those who made them; and yet as much may be frequently collected from the manner in which the evidence is delivered, as from the matter of it." All this must be admitted to be just and true in respect to the mode by which the knowledge of mere matter of fact may be arrived at; but it may be fairly questioned whether the sifting method here described is best adapted for eliciting valuable scientific opinions.

I am by no means disposed to advocate the course pursued in France and some parts of Germany, of drawing up medico-legal evidence wholly in writing—a system the palpable abuse of which is so clearly shewn in the lengthened and prolix documents to which it often gives rise, amounting sometimes to the production of controversial pamphlets; but I do say, that the opposite practice which prevails amongst us, of confining the professional witness to mere *verbal statements*, controlled, too, by men of a different profession, and who are acknowledged not to be, generally speaking, persons of very extensive scientific attainments, is a course extremely open to objection.

Citing of authorities.—But this is not all: the medical witness is subject to still fur-

the restriction on another point: he is often prevented from citing authorities. He may not state the opinions of the greatest names in medicine in corroboration of his own—no vouchers, whether ancient or modern, for the correctness of his assertions, may be tendered, if it so please the bar and the bench. It is not easy to conceive any thing more absurd or unfair than this; for, in the first place, it is perfectly ridiculous to expect a medical man, in giving evidence, to state nothing but what he knows through his own experience: were professional witnesses always limited to this, their utility in courts of justice were scanty indeed,—for who could, or should, venture to offer an opinion on any difficult point of diagnosis or practice that has not been adopted from, or confirmed by, the experience of others? If given as purely his own, all rational men must know what value ought to be set upon it. Nor is the unfairness—the injustice of the practice—less striking: for the members of the legal profession should, of all men, be aware, and are aware, that individual opinion is worth nothing unless it be shown to be in accordance with precedent, and consistent with reason, that is, as the lawyers usually understand it, consistent with the expressed sentiments of the Cokes, the Hales, and the Eldons, of their profession.

This was well pointed out on one occasion by a medical witness whose quotation of authorities was demurred to. At the trial of Mr. (afterwards judge) Cowper, for the murder of a lady who was found drowned, Dr. Crell, among other witnesses, was called upon for his opinions as to the likelihood of death being caused by drowning, little or no water having been found in the body. "My own opinion," said Dr. Crell, "is, that a very small quantity of water, not exceeding three ounces, is sufficient to drown any body; and I believe that the reason of the suffocation, or of any persons being stifled under water, is from intercepting of the air, that the person cannot breathe, without which he cannot live. I shall give you the opinion of several old authorities on the point." The judge (Baron Hatsell): "Pray, Doctor, tell us your own observations." "My Lord, it must be reading as well as a man's own experience that will make any one a physician; for without the reading of books of that art, the art itself cannot be attained to. Besides, my Lord, I humbly conceive that in such a difficult case as this, we ought to have a great deference for the reports and opinions of learned men; neither do I see any reason why I should not quote the fathers of my profession in this case, as well as you gentlemen

of the long robe quote Coke upon Littleton in others." And, accordingly, he proceeded to cite the authority of Ambrose Paré on the point in question; nor was such evidence in this instance refused.

On the other hand, when at the trial of Donnal (in 1817), Dr. Neale quoted the celebrated chemist Thenard, the judge (Abbott) objected, saying—"We cannot take the fact from any publication; we cannot take the fact as related by any stranger."

But there seems to be no fixed rule on the subject: while some judges have thus prevented, others have permitted the citing of published opinions, and have sometimes themselves appealed to authorities—to Dr. William Hunter, for instance, or to Haller, or Mead. Nay, on one occasion, when a medical witness flippantly uttered an opinion in court to the effect that the information in certain medical works on a particular subject was good for nothing—"that the writers of books would advance anything,"—the judge (Dallas) reprimanded him, and said that he would not sit in a court of justice and bear science reviled, and the recorded researches of the medical world represented by ignorant tongues as leading only to uncertainty*.

The objection commonly urged by lawyers seems to amount to this, that opinions and statements laid down in books, however eminent the authors, are only like so much hearsay evidence, not sworn to, and therefore not legally admissible. The unreasonableness of such a doctrine is obvious; for who shall assert that the deliberately published opinions of a respectable author are in any manner the weaker for not being confirmed by an affidavit; or that his statements are the less to be relied on for not being sanctioned by an oath? Some would even hold the very reverse.

In Scotland a greater latitude is allowed to professional witnesses: authorities are permitted to be freely quoted; and Dr. Beck informs us that in America no objection to such a course has ever been made. "There is scarcely a case of any note," says he, "where medical testimony has been required, in which frequent reference has not been had to medical works. They are quoted and commented upon by the bench, the bar, and the professional witnesses."

Notes to aid the memory.—There is another point on which the practice of our English courts is better defined, and apparently founded on more just principles. I allude to the *notes* which the medical witness is sometimes permitted to make use of. It is agreed that where those notes

* AMOS; MEDICAL GAZETTE, vol. vii. p. 613.

have been made immediately upon the occurrence of the facts to which they refer, they may be used in evidence, for the express purpose of *refreshing* the witness's memory. Thus the account of a *postmortem* examination drawn up by the witness at the time it was made, or the memoranda noted down presently after a transaction in which he has been engaged, are admissible afterwards in evidence. But where a person summoned to give his testimony in a court of justice relative to incidents that have happened, perhaps many years previously, sits down and compiles a written statement of what he knows or recollects of the matter, he will not be allowed to avail himself of such statement at the trial.

Want of attention to these points has often led witnesses into unpleasant difficulties: ridicule and reprimand, too, have been the lot of some who have come into court confidently relying on the complete proofs they had to bring forward, these proofs being probably memoranda neither made by themselves, nor under their inspection. It is not absolutely necessary that the memoranda alluded to should be noted in one's own hand; but in such case it is indispensable that the witness should have personal cognizance of the act of making them. If they be entries in registers which are adduced, the witness must either have made them himself, have seen them made, or be able to produce the parties by whom that office has been performed.

All this is calculated to inculcate the importance of carefulness on the part of our profession, and to recommend the practice of keeping journals or memoranda of the transactions in which we may be personally concerned. As we are interested in the peace and security of families—as we are friends to humanity and justice—and as we value our own reputation, we are called upon not to omit so simple, yet so important a custom.

Even a prescription book has sometimes been serviceable in the absence of other documents. Mr. Amos informs us that in a case in which he was engaged, where the trial was concerning a *will*, a physician was able to throw great light upon the inquiry by means of a book in which he copied all his prescriptions, and which enabled him to trace the progress of the testator's health at a distance of more than a dozen years, when otherwise it is probable that his memory might have afforded him no assistance*.

Evidence of *dying declarations*, of which medical men frequently become the depositaries, can scarcely be given in an unex-

ceptionable manner if the witness have neglected to take a contemporaneous note of them in writing. That hearsay evidence is not admissible in our courts, is the general rule; but there is a marked exception in the case of dying declarations. What a person utters in his dying moments, or when he entertains a consciousness of approaching dissolution, is valid as evidence upon trials for murder. The principle is a just one, for it implies that the awful situation of the dying individual is equivalent to the sanction of an oath, and that the absence of sublunary interest, on passing into another world, dispenses with the necessity of a cross-examination. But it must clearly appear that such is the condition of the party; if there be hope, however faint, of recovery,—if there be expectation that the adoption of further remedies may prolong life, the declarations will be rejected. This was the case in respect to Mr. Scott, who was shot in a duel. The surgeon who attended him on his death-bed was about to give the dying declarations of his patient when the trial came on at the Old Bailey; but inquiries were first made as to the precise state of the patient, and whether any conversation had passed from which the sense he entertained of his situation could be inferred. The witness said, "The deceased asked me if his wound was necessarily mortal?—upon which I told him that his case was one of extreme danger; but that there had been instances where persons had recovered under such a wound. The deceased then said, 'I am satisfied.'” The declarations were overruled by the judges, inasmuch as the language of the surgeon had probably kept alive in his patient's mind some hopes, however faint, of recovery. And in another case, where the dying declarations had already been duly taken, but the patient afterwards wished that more medicine might be sent for, they were rejected, because not made after all expectation of life was extinct.

One or two other hints on the subject of dying declarations may be added—namely, that these forms of testimony should always be purely voluntary, and that the dying person ought not to be *induced* to supply matter of accusation against living parties. The interrogations also should not be of a *leading* kind, or such as require from the declarator only a simple expression of assent or dissent—a *yes*, or a *no*; for this may be fairly construed into a prompting of statements in which, though the patient may have acquiesced, he cannot be supposed to have felt any adequate concern. Besides, such a practice of questioning is only allowed in open court, under certain precise restrictions.

* MEDICAL GAZETTE, vol. vii. p. 547.

Question of privilege.—Having thus noticed the extent to which medical testimony is received as evidence, and the limitations to which it is usually subject, it may be interesting to inquire whether medical men have any peculiar privileges in courts of justice. In the first place, may they decline to give such evidence as would appear to compromise the honourable confidence reposed in them by families? Are they privileged not to divulge secrets professionally and confidentially communicated to them? This question has been decided in the negative. In the case of the Duchess of Kingston, who was tried for bigamy, in the year 1776, the professional attendant of her grace, Mr. Cæsar Hawkins, endeavoured to evade some questions put to him, on the ground that if he answered them, he would dishonourably betray his patient. But it was held by the House of Lords, in the language of Lord Mansfield, “that a surgeon has *no privilege*, when it is a material question in a civil or criminal cause, to know whether parties were married, or whether a child was born, to say that his introduction to the parties was in the course of his profession, and in that way he came to the knowledge of it. If a surgeon was *voluntarily* to reveal those secrets, to be sure he would be guilty of a breach of honour, and of great indiscretion; but to give that information in a court of justice, *which by the law of the land he is bound to do*, will never be imputed to him as any indiscretion whatever.” Other decisions have since corroborated this view of the question; and it is now generally understood that professional confidence, as a ground of secrecy, can only be urged in the case of counsel, solicitors, and attorneys, when employed as such,—on the principle that in such circumstances they become identified with their clients.

There is one privilege, however, which medical men possess—namely, that of not being obliged to state any thing that may criminate themselves. All witnesses, indeed, by the laws of England, are entitled to the same right of reserve; but peculiar indulgence in this respect seems to be extended to our profession. It is well known that a medical man who attends a party engaged in a duel, and is present at the combat, though only in his professional capacity, is considered in the eye of the law as an accessory, and may be put on his trial for murder. After the fatal duel between Col. Montgomery and Capt. Macnamara, in 1803, a surgeon of eminence who had attended one of the parties professionally, was arrested and sent to Newgate, by a warrant from the civil power, as a principal in the alleged murder, having been present on the occasion, and antecedently privy to it:

nor was he liberated from prison till the grand jury were satisfied that there was no sufficient ground for the indictment. But it rarely happens that the law, in this respect, is severely administered: the more ordinary practice is to dispense with the evidence which the medical attendant could give in such cases. On the trial of Mr. Patmore, second to Mr. Scott already mentioned, the surgeon who attended the deceased at the duel, was summoned to identify the prisoner then in the dock, arraigned for murder. And he would have heedlessly done so, had he not been humanely warned by the judge not to expose himself to a criminal prosecution, by answering questions which might compromise his safety. A few years since, at the trial of the seconds of Sir John Jeffcott, who shot Dr. Hennis, of Exeter, in a duel, a physician who was on the ground with the party, being called upon to give evidence, declined to do so, and the judge (Patteson) said he could not compel him.

CONDUCT OF MEDICAL WITNESSES.

I have already alluded to the importance of circumspection on the part of medical men in giving evidence—no matter how humble the court may be in which it is tendered: for if it lead to the committal and subsequent trial of the prisoner, the depositions will be forthcoming, and contrasted with the mature testimony of the witness. But there are some other hints respecting conduct, which it may be well to observe.

Self-possession.—We should beware of being over-officious, or too profuse in giving our testimony, for thereby we expose ourselves to the imputation of some motive, perhaps of a personal nature, in the issue of the cause. Nor, on the other hand, should we be too reserved—too costive, in our information, for this throws us from Scylla into Charybdis, and we become liable to the suspicion either of shallowness, or a design to conceal from the court some important particulars. The golden medium, in this as in most other things, is to be preferred. We should reply freely and cheerfully to the questions proposed to us, with self-possession, but with perfect submission to the tribunal before which we stand. Self-possession is necessary, for the consequence of its absence may be serious. “A scientific witness,” says Dr. Paris, “fully acquainted with the subject in dispute, and by his particular knowledge well qualified to inform the court on the most important points, is too frequently rendered miserable to himself, and absolutely ineffective to the ends of justice, by the diffidence which a man of real

acquirement generally feels, when impressed at once with the novelty of his situation, a sense of the importance of the duty which he is about to perform, and a consciousness that the truths he is about to utter may be obscured, suppressed, or perverted, by technicalities for which he is unprepared with any defence: we do not mean to arraign the present forms of examination in general, when we assert that some abuse in practice too frequently places the witness in as painful a situation as if he were himself a criminal."

Technical terms to be avoided. — But it is not of the technicalities of the law alone of which the medical witness had need to be apprehensive; those of his own profession, if not guarded against, will most probably entangle him quite as much. Both for counsels' sake, who are said to be generally "very shallow men of science," and for our own safety, which so much consists in the integrity of our reputation, we had better abstain from the use of terms purely medical, where we can find others more popular that are at all suited to our purpose. The advice of my learned friend, Mr. Amos, on this point, is excellent. "When in the witness-box, drop as much as possible the language which is known only to scientific men, and adopt that which is in popular use. If you have occasion to speak of a person fainting, do not say, as I have heard it said, that you found the patient in a state of *syncope*; and you must not expect a court of justice to understand you if you talk of a person being *comatose*, and of the appearance of his stomach after death being *highly vascular*, or of your having discovered poisonous ingredients in his intestines by means of a *delicate* test. The judge and counsel are generally very shallow men of science, and it is a great advantage for them to raise a laugh at persons whom they would represent to be using hard names for common things. Veterinary surgeons are a great game for counsel; and I remember, in particular, a veterinary surgeon, who, when cross-examined by Serjeant (now Baron) Vaughan, was so unfortunate as to make use of the term *suspensory ligament*, which the serjeant interpreted into the 'hangman's noose.' In general the witness is called upon to define, as he goes along, the technical terms which he employs, and it is ludicrous sometimes to hear the words of which an explanation is gravely demanded. I have heard a learned chief-justice ask what the witness meant by an *injection*, where the context would seem scarcely to leave a loophole for doubt: the reply, however, that it was a *clyster* appeared satisfactory to his lordship; not, perhaps, because the

Greek name was more intelligible than the Latin, but that the former was the more common, and it was probably the wish of the court to discountenance all technicality. Of the opening for ridicule afforded by the use of certain terms, I cannot give you a better instance than one which was lately related to me by a friend learned in the law. A conceited shallow witness, a member of our profession, in undergoing the ordeal of cross examination, on a recent occasion, happened to drop, among other ill-assorted terms which he seemed proud to use, the word *dyspepsia*; the counsel, who was a wag, immediately seized on it, and raised roars of laughter at the witness's expense, by putting to him a question which he was unfortunately unable to answer — "Unde derivatur *dyspepsia*, Doctor? Eh, Doctor, unde derivatur *dyspepsia*?"

Ought witnesses to be made up for the occasion? — A general subject of complaint brought against medical witnesses, is the contradictory nature of their opinions, as given in courts of justice. Much of this, no doubt, is owing to the difficulty of the questions on which those opinions have to be delivered: but perhaps still more to the witness's want of preparation. Of the necessity for individual preparation there cannot be a doubt, when it is considered that the professional man is not called upon to testify to mere matter of fact: he has an opinion to deliver, and will be expected to state publicly the grounds of that opinion. Nor does there seem to be much more question regarding the propriety of joint preparation, when two or more witnesses are to be examined, touching the same subject of inquiry. Of the correctness of this position we have a strong proof in a case related by Dr. Percival. "Several years ago, a trial of considerable consequence occurred, relative to a large copper-work; and two physicians of eminence were summoned to the assizes to bear testimony concerning the salubrity or insalubrity of the smoke issuing from the furnaces. The evidence they offered was entirely contradictory. One grounded his testimony on the general presumption that the ores of copper contain arsenic, and consequently that the effluvia proceeding from the roasting of them must be poisonous, because arsenical. The other had made actual experiments upon the ore employed in the works under prosecution, and on the vapours which it yielded: he was thus furnished with full proof that no arsenic was discoverable in either. But the affirmative prevailed over the negative testimony, from the authority of the physician who delivered it: an authority which he probably would not have misapplied, if he had

been antecedently acquainted with the decisive trials made by his opponent."

That medical men are expected to make due preparation for giving ample and satisfactory testimony, is certain, at least in some instances, from the fact of the judge who has to try particular cases, having given directions to medical witnesses to make certain experiments on animals previously to the day of trial; a fact which serves to establish the principle, if, indeed, there could be any reasonable doubt of the excellence of the practice. The only point in connexion with the subject, on which a question can feasibly be raised, is as to the extent to which the minds of the witnesses should be made up anterior to the trial; for some have advised that they should come to a fixed decision, so as to prevent the possibility of differing when the investigation came on in public. But even were this practicable, it seems doubtful how far it were just and proper; for what would it amount to other than to inquire with a foregone conclusion, and thus to make a mockery of justice?

The practice usually observed with regard to medical witnesses in courts of justice, allowing them to remain during the trial, while other witnesses are secluded till called to give their testimony, is a still further proof of the wish of the court to obtain consistent evidence from the medical men. But it is curious to observe, that, in Scotland, the professional witnesses are *secluded* during the trial, for the very same purpose. "In the Scotch courts (says Mr. Alison, in his *Practice of the Criminal Law*) it is usual, when one medical man begins to give an opinion on the case, to cause the other medical men to retire. The reason of this is, that it has been found, by experience, that medical men, even of experience and information, are generally so prone to contradict each other, or to adhere to the side on which they are cited, that it is never safe to let them hear each other's testimony. The proper way to do, therefore, is to allow the medical men who are to be examined as to opinion, to hear the whole evidence relating to the facts, whether from the ordinary or the medical witnesses, and to remove them as soon as medical opinion is about to commence."

Of the mischievous absurdity of venturing into court to give evidence without previous preparation, I cannot close this part of my remarks without offering one or two examples. A man was indicted at the Assizes at Chelmsford, in March 1822, for having administered *copperas* to two women. The women had drunk two or three cups of tea, which tasted bitter, and in the evening were taken ill with a violent vomiting.

Next day their tea was still bitter, and some *copperas* was found on a plate in the house. One of the women suffered from the effects for about a month afterwards. It was attempted to be proved on the trial that *copperas* was a *deadly poison*, as laid in the indictment. A chemist of the town gave it as his opinion that the substance was not, properly speaking, a *deadly poison*, for the stomach would reject a dose sufficient to produce death before it would have that effect, and probably it would require two ounces, dissolved in water, to produce serious consequences; but still he did not think it would cause death. A physician, however, of Chelmsford, gave it as his opinion that *two drachms* of *copperas* would cause death. But on his cross-examination, it turned out that he was confounding *copperas* with *verdigris*; and he was obliged to confess his ignorance that copper did not enter into the composition of the poison alleged in the indictment!

This, it may be said, was an instance of pure indolence: the blunder of the physician was, perhaps, wholly attributable to his having gone into court without giving the slightest attention to the point on which he was to be examined. But I shall now show that too much care cannot be bestowed on preparation, and that even the most expert cannot calculate upon having it all their own way on these occasions. In the example I am about to adduce, we find a chemist of the highest reputation unexpectedly called upon to put forth his best abilities in his cross-examination by counsel. The gentlemen of the bar, it may be observed, are sometimes more than a match for the most intelligent witnesses who come before them; being often *crammed* for the purpose: and the conflict under such circumstances is always unequal. The professional witness is held to be fair game; and he is supposed to have no cause to grumble, as he is attacked on his own ground, and with weapons like his own. On the other hand, the counsel, whatever be the issue of the contest, comes off scatheless: and he has no risk of character to apprehend even from an exposure of gross ignorance in his cross examination.

At the trial of Stewart and his wife, in 1829, for the murder of a man, by giving him laudanum in strong ale, Dr. Ure, who had attended the post-mortem examination of the body, was summoned as a witness for the prosecution. The Doctor was positive as to the presence of opium in the contents of the stomach, from having relied on perchloride of iron as a test for meconic acid, and procured what he conceived to be the characteristic cherry red colour. He

did not know at the time (though, by the way, the fact was then far from new, Tiedemann and Gmelin having published it some years before) that the test he employed was rendered doubtful by the circumstance that human saliva contains a substance—the sulpho-cyanuret of potassium—which strikes the same red colour with the same salt of iron,—as indeed it is now perfectly well ascertained that there are other matters which might easily happen to be present in the stomach—such as mustard, &c.—which would also render the test fallacious, in consequence of their presenting a similar appearance. Dr. Ure, however, not being acquainted with the fact respecting the saliva, was taken wholly by surprise when the counsel for the prisoners urged upon him the inefficacy of his salt of iron test, since sulphocyanic acid also struck a cherry red colour, when treated with perchloride of iron. In a paper in Brande's Journal for 1830, Dr. Ure adverts to the facts of the case, and the objection raised by his cross-examiner:—"I was not then aware (says he) that this curious acid (the sulpho-cyanic) existed in the saliva, and I thought it merely a *ruse de pluideur*." There is reason to believe that the "ingenious counsel" was primed for the occasion, by a rival chemist of Glasgow; and probably the point urged might have had much weight, had not the medical witnesses been agreed, that, whatever ambiguity might attend the test employed, the characteristic smell of opium given out by the contents of the stomach, was too perceptible to leave any doubt on their minds. The moral circumstances of the case, besides, were very strong; so that the prisoners were found guilty, and executed.

General demeanour.—A few words on the general demeanour of witnesses, and I have done. It has been already seen how many difficulties beset the path of the professional man in coming in contact with our legal tribunals, and I have just noticed some of the perplexities and annoyances which may await him in court. It is scarcely surprising that the apprehension of the sort of treatment which they have reason to expect, should render most men "tremblingly alive" to their position, and that some should even be betrayed into intemperate or indignant sallies: but Dr. Haslam's suggestions are well deserving of consideration:—"The lawyer's object is the interest of his employer, and, for the fulfilment of his duty, he is frequently compelled to resort to a severity of investigation which perplexes the theories, but more frequently kindles the irritable feelings, of the medical practitioner. The distrust on the part of the lawyer, however

unpalatable, is fully justified, most witnesses going into court with the preconceived intention of *proving* to a certain extent; and those most conversant in the history of human testimony have been extremely scrupulous of admitting it as a uniform truth until it has been carefully sifted. Guarded with these precautions, and armed with professional experience, the medical practitioner may approach the tribunal of justice with confidence, and advantage to the cause of truth. However dexterous he may shew himself in fencing with the advocate, he should be aware that his evidence ought to impress the judge, and be convincing to the jury."

Unhappily there are but too many instances on record of this disposition on the part of medical men to fence with the gentlemen of the bar: in some cases a contest in "the flowers of Billingsgate" has been attempted; the result has always been to be deplored. But I shall forbear to bring such examples before you, however powerfully they might serve as a warning to remain on all such occasions cool, steady, and collected; and to impress you with the necessity of keeping your temper. To the danger of assuming an affected manner, or the appearance of false dignity, I need hardly advert; it is hazardous at any time to venture before the public out of one's proper character; in a court of justice it may be ruinous. In short, the golden rule of conduct seems to be—to preserve our natural manner—to have just so much confidence as may arise from the consciousness of being not unprepared—and, above all things, to be calm.

ON THE

THERAPEUTICAL EFFECTS OF IODINE,

GIVEN IN VERY LARGE DOSES,

In the forms of Iodide of Starch, Hydriodic Acid, and Iodide of Potassium.

BY ANDREW BUCHANAN, M.D.

Junior Surgeon to the Glasgow Royal Infirmary.

IN a former number of this journal (vol. xviii. p. 515) I pointed out a new method of administering iodine, by means of which it may be given with safety in doses much greater than by the ordinary modes of administration. I likewise described the principal physiological effects resulting from the use of iodine in such doses. I am now to attempt the more difficult task of forming an estimate of the virtues of iodine in the cure of disease, in so far as the observa-

tions made in the surgical wards of the Glasgow Infirmary enable me to do so.

The principal surgical diseases in which iodine was prescribed were syphilis, sибbens, scrofula, ulcers depending upon constitutional causes, noli me tangere, cancer, and tumors. It was also tried in lepra, psoriasis, ichthyosis, impetigo, and porrigo, diseases not usually treated in the surgical wards, the patients being in the hospital for other diseases, or having been taken in for the express purpose of trying the efficacy of the remedy.

Of 37 patients to whom, on looking over the hospital journals, I find iodine was administered in one or other of the methods described above, it would be useless to give the cases of the whole, because several of them, from the ambiguous nature of the diseases with which they were affected, from other medicines having been previously employed, or from the iodine not being fully tried, do not furnish any satisfactory conclusions. I shall mention only those cases in which the disease was clearly marked, and the efficacy of the iodine fairly tried.

Secondary Syphilis.

I shall first mention four cases of secondary syphilis.

Archibald M'Gillivray, æt. 24, shoemaker. January 7th, 1836: Contracted syphilis about three years ago. Since this, secondary symptoms have been obstinate, notwithstanding four or five complete courses of mercury, two of which he underwent in this hospital. About a year ago a node formed on each tibia, and some time afterwards one appeared on the ulna of the right arm. An eczematous eruption broke out on the face in July last: it was removed by means of sarsaparilla and mercury, but reappeared about three weeks since on left superciliary ridge and chin. The node on left tibia becoming painful, red, and fluctuating, eight days since he had it laid open by a free crucial incision.

On admission the wound has an unhealthy appearance; granulations are glassy, and discharge consists of brown pus, tinged with blood. Surface of tibia is bare, rough, and irregular, in centre of wound, for the space of about half an inch in diameter; and a probe passes outwards beneath the integuments for a short distance. General health good.

Jan. 8th. — Sumat ter indies Iodidi Amyli, ʒss., ex haustu Decoct. Aven. Curet. Ulcus, Ung. Oxid. Hydr. Rubr.

13th.—Iodine agrees well, and urine strongly impregnated with it.

Augeat. dosis Iodid. Amyl. ad ʒj. ter indies.

20th.—Fresh eruptive patches on nose and right leg; node on left tibia and right ulna diminished in size, and free from pain. Medicine agrees well, only it renders him costive, for which he has had a laxative several times.

Feb. 20th.—About eight days ago salivation and swelling of the face came on. Since yesterday has spat upwards of a pint of saliva, which is as strongly impregnated with iodine as the urine. Two small ulcers on inside of left cheek; nodes gone, and eruption where ulcerated has now healed; sore of leg looks better, but there is still bare bone in the centre of it.

Ossi nudato adhibeatur Acid. Muriatic. Dilut.

March 12th.—Salivation subsided soon after last report, and sore of leg healed very speedily after the bare bone had been dissolved away by the muriatic acid.

Dismissed cured.

James Kilpatrick, æt. 34, flesher. March 30th: About three months ago observed several warty excrescences forming around anus; his attention being called to them in consequence of the irritation they produced. A week or two afterwards observed purulent matter exuding from below prepuce, and, on examination, he found superficial ulceration behind corona glandis. On admission ulceration is still found in this situation; discharge is thick pus. Prepuce is somewhat swollen, and orifice contracted. On scrotum, body of penis, inside of thighs, and around anus, is an eruption of ulcerated patches, which appear to have commenced in slightly elevated round spots, about half an inch in diameter; these became excoriated on the surface, and, by coalescing, have assumed irregular forms in several places. The discharge is thin and sero-purulent; parts are the seat of considerable itchiness; throat is in a state of superficial ulceration, and right tonsil is much enlarged. Scattered over the body and upper extremities are a few blotches of a coppery hue. Had

gonorrhœa about three years ago, but denies ever having had chancres before. Never used mercury.

March 31st. — Sum. ter indies Iodid. Amyl. ʒss. Ficus circa anum et ulceribus scroti adhib. Vapor Iodinii, et postea Ung Periodidii Hydr.

April 29th. — The dose of iodid. amyl. was increased to one ounce, but it was found to occasion looseness of bowels; he has therefore taken it for the most part in ʒss. doses. All the symptoms of the disease for some time gone.

Dismissed cured.

In the two following cases the iodine was given up, and mercury substituted, on account of the venereal eruption not going away, but, on the contrary, fresh patches of it appearing. I would not now, however, consider this a sufficient reason for stopping the iodine. In the case of McGillivray, detailed above, in which a complete cure was ultimately effected, fresh patches of the eruption came out when the patient was fully under the influence of the medicine. Dr. Lawrie informs me that he has so often made the same observation, that he considers the fresh eruption as by no means an unfavourable symptom; and he has further remarked, that it is only in cases of syphilis that any eruption shews itself under the use of iodine.

David Struthers, æt. 32, weaver. December 21st, 1835: Surrounding anus and between nates is a collection of small round superficial ulcers, slightly raised at their margins. The discharge is thin, sero-purulent, and irritating; intervening integuments red and tender. Several ulcers of a similar character are scattered over scrotum and integuments of penis.

Contracted sores from impure connexion about ten weeks ago; these are still open behind glans, near left side of frenum. Disease appeared around anus about nine weeks ago; and about a fortnight ago a lichenous eruption broke out over arms and body, accompanied by itching. No treatment.

Sum. ter indies Iodid. Amyl. ʒss.

27th. — Medicine agrees well. Urine abundant, and becomes as black as ink on addition of starch and nitric acid.

Unguent. dos. ad ʒj. ter indies.

January 11th. — For fifteen days took ʒij. of iodid. amyl. daily: it appeared to render bowels costive, requiring the

use of castor-oil. Stools somewhat whitish. Took last dose on the morning of 6th instant; tinge of iodine continued in the urine till fifth day after. Little change upon eruption or sores.

Rep. Iodin. sed Sum. solummodo, ʒss. ter ind. Curent. Ulcera Ung. Iodin.

February 2d. — Iodine has agreed better in diminished doses. Ulcer around anus nearly healed, but little change on blotches of the skin, and two new ones have appeared on scrotum.

Omit. Iodin. — Sum. Pil. Hydr. ij. V. et i. M.

16th. — Cured.

The other case is that of a man (James Hare, Ward No. 12), who was admitted for strumous sores in the groin, originally excited by venereal infection. He was put upon the beautiful new salt of iron, discovered by Mr. Graham — the peroxalate of iron and potass; which appeared to act very effectually as a tonic, and was given in gradually increased doses, till he took of it gr. xv. twice a-day. He was next tried with iodide of starch, which was given at first in very small doses, as he was one of the first patients to whom it was prescribed. The dose was gradually increased, and when he was fully under the influence of the medicine, a copious eruption of blotches took place all over his body. The iodine was in consequence intermitted, and first sarsaparilla and afterwards mercury substituted; under which remedies the cure was effected.

Sloughing Sores of Penis.

Four bad cases of this kind were treated with iodine, and all of them did well. These patients were Smith, M'Kittrick, Norie, and Macdonald; all of them in Ward No. 7. The two first used the iodid. of potassium, in ʒj. doses; the two last the iodid. of starch, in ʒj. doses. It is to be remembered, however, that strong nitric acid as a caustic, opium, and other remedies, were also employed; whence it is very difficult to estimate the value of the iodine. I shall not, therefore, insert these cases, but merely say that my impression was in favour of the utility of the iodine.

In an exceedingly severe case which I saw in private, along with Dr. Black, Kent-street, the iodid. of potassium seemed also to be of service; but the

strong nitric acid being here likewise employed, there was the same room for scepticism.

The only other case of syphilis to which I shall advert is that of M'Gregor, (Ward No. 7); in which mercury was prescribed in the first instance, and to it the cure was undoubtedly to be ascribed. I only mention this case to illustrate the effects of iodid. of potassium introduced by inunction. An ointment was formed, containing 3j. of iod. potassii to ʒj. of lard. With this ointment the patient was directed to smear over the whole surface of the body. He used ʒss. of the ointment at night; and the other ʒss. next morning. At the hour of visit, no iodine could be detected in the urine. He was in consequence directed to rub in a whole ounce of the ointment that evening and next morning. In the urine passed in the morning before the second inunction, there was merely a trace of iodine, while in that passed after mid-day it was exceedingly abundant.

Sibbens.

Considering the efficacy of iodine in syphilis, it was natural to infer, from the analogy of the two diseases, that it would likewise prove an useful remedy in sibbens. It was accordingly tried in the following case, and the result was highly satisfactory.

Hugh Macgregor, æt. 33, farmer, Balquidder. April 12th: On left side of isthmus of throat, occupying both pillars and the intervening space, and stretching over front of uvula, is a patch of superficial ulceration, with slightly elevated edges and indolent surface, covered with a yellow exudation. Uvula is much relaxed, and from part of the velum on the left side being destroyed, it inclines to the right. Parts in the neighbourhood of sore are of a dusky-red colour. Ulceration appeared about 3½ months ago, and was treated with mercury, with good effect. It did not continue well, however, above a fortnight; ulceration reappearing and spreading to a greater extent than before. Denies all syphilitic taint, and attributes his complaint to eating from the same dish and smoking the same pipe with an infected person. About ten years ago was much troubled with cynanche tonsillaris, advancing on the last attack (seven years ago) to suppuration.

Sum. Iodid. Amyl. ad ʒss. ter indices.

15th.—Augeat. dos. Iod. Amyl. ad ʒj. ter indices.

May 4th.—Dismissed cured.

Scrofulous Affections of Joints and Bones.

The most formidable diseases of the scrofulous kind which come under the cognizance of the surgeon, are the affections of the joints. The most common of those affections is that which originates in the ends of the bones forming the articulation, by the deposition of tuberculous matter in their cancellous structure. In one case of this kind, the iodide of potassium was prescribed, in the dose of ʒij. daily; but, in consequence of the medicine disagreeing, it was intermitted before any judgment of its efficacy could be formed. It will be seen, however, below, that in diseases of the same nature, only existing in bones not entering into the formation of any large joint, the iodine was decidedly useful. In the scrofulous thickening of the synovial membrane, another disease of the joints not less intractable, and in this part of the country little less frequent than that just mentioned, the trials made of the iodine were unavailing, as illustrated in the following case.

Jane Montgomery, æt. 12. January 19th: Right knee-joint is much swollen, measuring fully an inch in circumference more than left. Form of joint is lost, the shape of patella being obscured in consequence of surrounding tumefaction. Above patella, and also on inside of knee, opposite head of tibia, there is evident fluctuation. These fluctuating swellings do not communicate with each other. There is also a fluctuating spot, small in size, on the outside of head of tibia. Limb partially flexed, and any attempt at extension produces pain. Little or no uneasiness is felt on pressing the articulating surfaces together, nor does pressure on the extremities of the bone excite much pain. Complaint is of about twelve months' duration, and has been treated with counter-irritants, with relief to the pain, but without benefit to the swelling. General health impaired; occasional night sweats; pulse 124.

Feb. 2d.—A blister applied over joint, with diminution of pain; tongue clean; appetite improved.

Sum. Iodid. Amyl. ʒij. ter indices.

18th.—Little change upon knee; elastic swelling on the outside of it less

distinct, while that over inner head of tibia has more feeling of fluctuation. Pulse averages about 125, appetite good, tongue clean. Less pain of knee; medicine agrees well, and urine strongly impregnated with it.

24th. — Three days back, much increase of pain of knee, with increased swelling, and redness of surface; pulse 144; tongue clean, but appetite impaired.

Leeches twice applied to knee, and iodine stopped.

28th. — On 25th, at a consultation, it was recommended to delay amputation, and to puncture the fluctuating tumor over head of tibia. This was accordingly done, and about 3ss. of curdy matter discharged.

March 15th. — Amputation was determined on at another consultation, but the parents refusing to give their permission, the girl was removed at their desire.

The following case was one of those in which the virtues of iodine were most remarkably exemplified. It will assist the mind in forming an idea of the appearance of the diseased parts, to mention that several medical gentlemen, who saw the case when first admitted, thought that partial amputation of the hand was the only remedy likely to be of any use.

John Elliot, æt. 24, sadler: Aug. 4th. Twelve months ago an abscess formed on back of hand, above the thumb, which burst some time after, giving exit to a considerable quantity of pus. About same time an abscess formed over ball of right thumb, which was opened.

On admission, there exists over hand a large strumous-looking ulcer, intersected by undermined bands of skin, and secreting thin unhealthy pus. Hand is the seat of considerable aching pain. Through a part of this ulcer metacarpal bone of index finger is detected in a carious state; over ball of thumb are also two openings of the same character, but through neither of these is bone found bare.

Left knee-joint measures an inch more than right in circumference. Swelling principally confined to the bursa above patella; there is apparently but little affection of the synovial membrane around the knee; head of tibia is the seat of a good deal of pain, especially when pressed upon. General health pretty good; diathesis strumous.

Sum. Ol. Ricini, ʒj.; et parti genu dolenti adhibeatur Empl. Mel. Vesic.

Aug. 16th. — Knee much improved by blister; little change in sore of hand.

R. Iod. Potassii, ʒj.; divid. in pulv. xij. Sum. j. ter in dies.

R. Iodinii, gr. x. Axungiae, ʒj. M. Fiat ung. quo curet. Ulcus.

Aug. 19th. — Augment. dos. Iod. Potass. ad gr. x.

Sept. 10th. — Iodine ointment not applied, sores having been dressed with a poultice all along. Has taken iodic. potassii in gradually increased doses, and for a fortnight has taken ʒj. daily; medicine found in large quantity in his urine. Sore nearly healed; no carious bone discharged. Continue.

Sept. 14th. — Sores quite healed; dismissed, cured.

In the two following cases the use of the iodine was conjoined with a local application, which appears to me to be of much service in the treatment of many cases of carious bone. I allude to the application of diluted muriatic acid used altogether as a chemical remedy, for the purpose of dissolving away the exposed bone. In this way portions of bone which are keeping up a lingering disease may be removed more speedily than by any other means, save excision. I have already mentioned one instance of an obstinate sore upon the tibia, which was cured by means of the acid very speedily, and certainly with far less pain to the patient than could have been accomplished by the saw or the gouge. I have found an acid of the strength of the acid. muriatic. dilut. of the Pharmacopœias, to have a solvent power sufficiently energetic, and at the same time to occasion very little irritation of the soft parts in the neighbourhood. It may be conveniently applied by means of a long glass tube, which should be about half an inch in diameter, and drawn out at the lower end, so as to be little thicker than a probe; or it may be applied by means of an apparatus like that used in the laboratories for washing precipitates from the sides of the funnel.

John Kenney, æt. 16, piecer. Feb. 6th: About 10 months ago, after a slight injury, right foot became swollen, but without pain, redness, or constitutional affection. A short time afterwards, small abscesses formed on outside of dorsum, and on the sole. Some were opened

by puncture, and others allowed to burst spontaneously. Since this they have assumed an indolent character, shewing no disposition to heal, and discharging thin sero-purulent matter. Through two of those, on the dorsum, diseased bone can be detected. Into one of those on the sole, probe can be passed $1\frac{1}{2}$ inches without detecting bone. The others are more superficial, extending but a short way beneath surface. Experiences no pain or uneasiness in the foot. A small sinuous abscess of a strumous character exists on neck, beneath left angle of the jaw, discharging thin matter, mixed with curdy flakes. Probe passes for about an inch under integuments, which are red and thin. General health somewhat impaired, with occasional rigors, but, he says, no night sweats. Pulse 108; tongue clean.

At a consultation held upon this case, partial amputation of the foot was recommended, but I preferred trying the effect of medicine in the first instance. Half an ounce of the liquid hydriodic acid was prescribed three times a day, and soon after the local application of the dilute muriatic acid was begun. In the course of three weeks the diseased bones were partially dissolved and softened, but the fever did not abate, and the boy's friends, apprehensive of an operation, had him removed from the house.

Ann M'Eachern, æt. 27, March 16th: On left forearm are situated several ulcers, varying in diameter from half an inch to an inch and a half. The largest, situated on the anterior aspect, presents an indolent disc, covered with pale flabby granulations. Edges are sharp, and slightly elevated. The others have thin slightly-livid margins, and are without any appearance of granulations: the discharge which issues from them concreting into yellowish green scabs. Through one, situated over lower third of ulna, probe passes, detecting rough bone, and in June last, a fragment of bone, about two inches in length, was discharged from this spot. Skin of nearly whole of forearm is altered in appearance, from the cicatrization of former ulcers. On left clavicle is a large narrow sore of a similar character, with large one on forearm.

Those on the arm are of several years' duration; that on the clavicle appeared about six weeks ago, from the bursting of a small abscess. Right knee-joint is

somewhat swollen, swelling being soft and fluctuating, and presenting itself principally on either side of patellar ligament and tendon of rectus femoris. Patella is raised from the condyles. Motion of joint is unaffected, and disease is productive of little or no uneasiness. It appeared about a year ago, without evident cause. General health pretty good.

Sum. ter indices Iodid. Amyl. \mathfrak{zss} . more solito.

March 31.—Iodine intermitted, on account of slight febrile attack. Has since recommenced the use of it. Sores somewhat better; ulna still bare.

Ulnæ adhib. Acid. Muriat. dilut. Cont. Iodin.

April 28th.—Cured.

Scrofulous Ulcers all over Body, without Diseased Bone.

Jean Banks, æt. 29.—On left arm are several ulcers, varying in size from an inch to a few lines in diameter. The edges are thin and well defined; discharge consists of thin pus, which concretes into dark greenish-coloured scabs. Integuments surrounding sores of a reddish hue; around left knee-joint are several sores of a similar character. Complains of occasional severe pain in sores, especially those on the leg. No diseased bone can be detected with the probe. Four years ago, sores of a similar kind appeared on right ear and angle of jaw; they healed in about two months. Disease again broke out on nose, left cheek, arms, and legs, which places are completely covered with scars. Has undergone a variety of treatment; general health somewhat affected. Catamenia absent since attack.

Sum. ter indices Acid. Hydriodic. \mathfrak{zss} . ex. haustu solutionis Amyli. Ulceribus adhib. Cataplasma et post. Ung. Ox. Hydr. rubr.

February 28th.—Sumat. pulv. Rhei & Magnes. \mathfrak{zij} .

March 27th.—Sores around knee-joint nearly healed, as well as those on arm. Soon after admission five front teeth of upper jaw were found to be loose, and there is now a discharge of matter from root of second incisor. The hydriodic acid frequently intermitted, on account of irritability of stomach.

Extrahatur dens incisor. Repet. Acid. Hydriod. dosibus, \mathfrak{ziii} . ter indices.

April 12th.—Dismissed, cured.

Specific Ulcers.

Under this indefinite title I do not comprehend the scrofulous and venereal ulcers which have already been spoken of; but certain anomalous forms of ulceration which seem to be dependent upon a defective state of the general function of assimilation, as they derive little benefit from mere local applications, and can only be cured by remedies acting on the system at large. It was in the cure of such specific ulcers that the virtues of iodine were most signally displayed.

John Balfour, æt. 20, weaver. January 4th: On ulnar aspect of lower half of left fore-arm is a large irregular ulcer, with slightly inverted edges, and an irritable surface. Discharge is thin, and occasionally tinged with blood. Surrounding integuments slightly discoloured. Sore commenced about four months ago, in the form of a few ecthymatous pustules, which suppurated, burst, and ulcerated, and it has been spreading since by the formation of new pustules around margins. On legs and arms are a few patches of eight days' standing, which have suppurated and scabbed, and seem to be disappearing. Had primary sores about two years ago, with sore throat some months afterwards, which was treated with mercury pushed to salivation. Has at present a muco-purulent discharge from the urethra, which he thinks is of two years' duration.

Sum. ter indies Iodid. Amyl. ʒss. more solito.

Jan. 16th.—About one-half of sore has healed, and the rest looks very healthy. Bowels somewhat bound, and complains a little of pain of belly.

Sum. Ol. Ricin. ʒss.

The sore healed completely not long after above report, when the treatment was altogether directed to the removal of the ecthymatous eruption, which proved very obstinate.

Margaret M'Gillivray, æt. 20, steam-loom weaver. March 1st: On middle and upper third of left leg, and occupying outer and posterior aspects, are several ulcers, varying from a quarter of an inch to fully an inch in diameter. They are somewhat irregular in form; edges thick, white, and elevated, and their surface glassy. The upper one is deeper than the rest, probe passing into a small cavity in its centre for

about half an inch; surrounding skin of a livid hue.

Sores commenced eight months ago, in leech-bites, which were irritated by the application of a blister. Denies all constitutional taint.

Cataplasm. Emoll. Sum. ter indies
Iodid. Amyl. ʒss. Adhibeatur ulceribus Ung. Iodin.

March 30th.—Ulcers cicatrized rapidly, and are now nearly healed. They have not, however, made any progress for the last ten days, during which iodide of starch has been disagreeing with stomach, and, in consequence, little used.

Intermitt. Iodid. Amyl. Sum. Acid. Hydriod. ʒij. ter in dies more sol.

April 9th.—Dismissed cured.

Jean Macfarlane, æt. 15, servant. April 13th: On inner side of right ankle-joint is a patch of a honey-comb appearance, produced by an aggregation of small ulcers, averaging about one line and a half in diameter. Intervening and surrounding skin is somewhat red and swollen; discs are indolent, shewing little disposition to granulation, and their edges are thickened and slightly elevated. Appears to have had an attack of erysipelas about six months ago, giving rise to present affection.

Catapl. Emoll. Ol. Ricin. ʒss.

April 16th.—Sumat ter indies Iodid. Amyl. ʒss. Curetur ulcus Ung. Nitr. Hydr.

27th.—Dismissed cured.

[To be continued.]

OTIC GANGLION.

To the Editor of the Medical Gazette.

SIR,

I THINK it necessary to inform you, that since writing the observations which appeared in your number for July 30, 1836, I have discovered the otic ganglion, small but distinct, in the dog. It has only been found once after many dissections, and may, therefore, be considered of rare occurrence in that animal. This circumstance renders it probable that it may occasionally occur in

the cat, although my dissections hitherto have failed to demonstrate it.

I am, sir,
Your obedient servant,
J. H. BENNETT.

Edinburgh, Sept. 10, 1836.

LIVING EARWIGS INFESTING THE ALIMENTARY CANAL.

To the Editor of the Medical Gazette.

SIR,

As I have not seen on medical record an instance in which the common earwig was found to infest the intestine of a human being, perhaps the following cases may be interesting to your readers.

Very faithfully yours,
WM. GRIFFIN.

62, George-street, Limerick,
Sept. 25, 1836.

A young married woman had been complaining for some time of distressing headaches, for which I ordered her some purgative medicine. On my next visit she showed me an insect which she passed per anum. It was the common earwig, and corresponded, in every particular, with the characters assigned to the coleopterous insect of the genus *Forficula*. Dr. Pickells, many years since, related a very extraordinary case, in the Irish Transactions of the King and Queen's College of Physicians, in which enormous progenies of apterous, dipterous, and coleopterous insects were discharged both by the mouth and anus, but he does not mention the common earwig among them; nor could I readily bring myself to believe so formidable a little animal might infest the human intestine, without symptoms of greater distress and ill health than occurred in this woman's case. She declared to me, however, that she found it alive in the vessel which she made use of on her bowels being moved, and that it was not in it before then. I ordered her one or two doses of castor-oil and turpentine, with some relief to her head, but there was no further discharge of insects.

Considerable doubt might be entertained as to the fact of the insect having been discharged per anum in this instance; and I should perhaps have thought lightly of it, had it not been

for another case which my brother had been attending, and which I saw in the course of it, in consultation with him. The following is a copy from his notes on the subject:—

James Naughten, a pale delicate-looking lad, 12 years of age, was brought to the Dispensary, complaining of paroxysms of hysterical crying, with debility and loss of appetite. He was frequently attacked with severe fainting fits, which were often attended with spasms of an epileptic character. His tongue was whitish, pulse quick and weak, no thirst, his bowels quite free, and, according to the account of his parents, not suffering under any derangement.

The symptoms were at first attributed to general delicacy of habit, and he was ordered purgatives of calomel and jalap, and Epsom salts, with bitter infusion. These not appearing to serve him, the purgatives were repeated, followed by tonics. The same treatment was pursued, with some slight variety, for a month or six weeks, but without the least improvement.

At this time his mother brought him to the Dispensary, and showed two insects, which, she said, the boy had drawn from his throat with his fingers. They were of the coleopterous order, and, on examination, proved to be the common earwig. She said he had felt them running about his throat, and putting back two of his fingers, soon felt them passing round the ends of them; he then watched for the moment when they ran between them, and drew them out. They were living, and she described them as so swift that (to use her own words) "nothing could catch them." They died very speedily. She now said he was sometimes attacked with severe pain in the stomach and back of the neck, which he found much more violent than usual lately.

He was immediately ordered half an ounce of the spirit of turpentine, in a draught with mucilage, with directions to give him a dose of castor-oil three or four hours after it. The next time he applied he was a good deal better, and, upon inquiry whether he had seen any more of the insects, he said, when the medicine operated, he had passed "a hatful of them," all dead. Another dose, such as the former, with a course of tonics, entirely cured him.

A REPORT
OF THE
SURGICAL CASES ADMITTED
INTO THE LIVERPOOL NOR-
THERN HOSPITAL,

From the 25th August, 1835, to 25th August,
1836.

To the Editor of the Medical Gazette.

SIR,
In the sixteenth volume of the MEDICAL GAZETTE, published in 1835, page 87, you inserted a report of the surgical cases admitted into the Northern Hospital during the preceding year. Will you oblige me by admitting the report of the surgical cases for the last year, in an early number of your publication? In the note accompanying the last report I stated "that it was in contemplation to add thirty beds to the hospital;" this has not yet been done; consequently the number of beds remain the same, viz. thirty-seven. It will not be until October next that the hospital will be increased, when we shall be able to accommodate seventy-six patients.

I remain, sir,
Your obedient servant,
JOHN M. BANNER.

Liverpool, Sept. 13, 1836.

Nature of the Cases.
It will be seen that there were—
247 accidents.
134 fractures;
106 simple,
28 compound.
96 cases of disease.

Result.
Out of the whole number—
284 were cured.
4 dismissed incurable.
27 remain in the house.
28 died.

Occupation.

Of these cases there were—

136 labourers, porters, &c.
95 sailors.
53 masons, carpenters, &c.
59 women.

Country.

156 English; 90 Irish; 38 Welsh; 18 Scotch; 17 Americans; 3 Germans; 2 Swedes; 2 Prussians; 1 Dane; 1 Maltese; 13 unknown.

25 of the patients, when admitted with accidents, were in a state of intoxication.

There have been 29 operations performed during the year: 11 amputations, 9 from accidents, and 2 from disease.

The nature of the Accidents requiring Amputation.

CASE 1st.—A man was admitted with compound fracture of the tibia and fibula, a wound extending into the ankle joint, with severe hæmorrhage. On examining the foot after amputation, we found the ends of the tibia and fibula fractured in seventeen places; the anterior and posterior tibial arteries were wounded. During the operation the patient was very faint; the arteries were secured, as we supposed, and the patient placed in bed. He had not been in bed many minutes, when a severe hæmorrhage took place; the tourniquet was immediately applied, the dressings removed, but no bleeding vessel could be seen; the tourniquet was removed, and the hæmorrhage had ceased; the artery was now compressed high up the thigh with the fingers, the pressure suddenly removed, and a large jet was observed from the posterior tibial artery, which was immediately secured. The operation was performed by candle-light.

2d. A pilot had his foot caught in a coil of rope, when his boat was sailing very fast; the foot was nearly torn off, there was severe laceration of the leg, and fractured tibia and fibula.

3d. A sailor fell from the main-mast, and produced a compound fracture of the humerus. The bone was much comminuted, and there was a wound of the brachial artery: the fracture was close to the axilla.

4th. A plasterer fell from a roof, and produced a compound fracture of the tibia and fibula. Close to the knee-joint there was internal hæmorrhage; the leg was much distended with blood, and quite cold; the swelling extended

above the knee-joint. A large quantity of blood was effused between the muscles and under the integuments. The anterior tibial artery was wounded.

5th. Is that of a sailor, who met with a similar accident to the last. In this case the fracture extended into the knee-joint, which was also filled with blood.

6th. A child seven years of age was leaning over the side of a flat, at the time another was passing: his arm was caught between the two boats, and completely smashed: it was necessary to amputate close to the axilla.

7th. A Prussian sailor was carrying a heavy box: he let it fall, and with it was precipitated into the hold of the ship. He had injured his back and knee: there was effusion into the joint, and fracture of the fibula close to the knee. There was a clean wound over the cuboid bone, which could be felt fractured. The edges of the wound were brought together with adhesive plaster. For ten days the patient went on well; at the expiration of this time he complained of much pain in the foot, and exhibited symptoms of inflammatory fever. There was a watery discharge from the wound, which was offensive: the wound looked sloughy. The tongue was furred, and he was delirious; the pulse was quick and weak. In a few days a slough formed on the instep, and another over the inner ankle. The calf of the leg felt baggy; an opening was made into it, but without relief; there was the same thin offensive discharge. The symptoms became more aggravated; the tongue was brown and dry; the pulse remarkably quick and feeble. He lay in a torpid state: he would not answer questions unless roused; his breathing was laborious; he had low muttering delirium; there was little or no discharge from the foot; the sloughs had increased. A consultation was held, and it was thought that the patient was not in a fit state to undergo amputation. On the following day the symptoms were evidently more unfavourable, and he appeared to be dying. The tongue was black and quite dry; the voice weak, scarcely audible; the countenance anxious; restlessness of the extremities; the skin dry and hot, which had been the case from the first appearance of slough; the breathing was more difficult, and the pulse was more feeble and

fluttering. A consultation was held on this day. We agreed in thinking that the patient could not long continue in the state he was in; and although we thought that the patient might sink under amputation, yet we agreed in thinking that it gave him the only chance. The friends consented, and the leg was removed. Very little blood was lost during the operation, which was performed close to the patient's bed. He suffered less than might have been conceived, and did not faint: he suffered more in the removal from and to his bed, than from the operation. In twenty-four hours the tongue became moist, the pulse much reduced in frequency, and the countenance more tranquil, and he slept. It is unnecessary to follow this case throughout the cure: it is sufficient to state, that he rapidly lost all his unpleasant symptoms, his health improved quickly, the stump healed kindly; and in five weeks he left the hospital well.

8th. Was a compound fracture of the tibia, near the ankle joint, and fracture of the fibula at its upper third. The patient had been a hard drinker, and was admitted in an intoxicated state. The leg was placed in a junk: he appeared to do well for two days, when delirium tremens came on; this was considerably increased by the circumstance of a rat falling through the ventilator, which was situated over his head: it so alarmed him, that the idea of his being devoured by rats could not be got rid of for three days. By the use of opium and stimulants this affection left him. On the eighth day he was attacked with traumatic delirium: he had violent spasms of the muscles of the extremities and face: this tetanic affection increased, and it was thought proper to perform amputation. When the spasmodic symptoms subsided, he was occasionally affected with delirium. The stump was an unhealthy one; he gradually became weaker; and on the tenth day after amputation died. On examining the leg, after the operation, the fibula was found fractured very obliquely, and the muscles in the neighbourhood of the fracture were dark-coloured and much torn: this probably arose from the restlessness of the patient, and from the spasmodic action.

It will be seen by the list of cases, that there have been eight burns and

scalds admitted: three of these died; two severe burns, and one scald, which was accompanied with nervous delirium.

Out of the fourteen cases of fractured skulls, ten died, each within two hours of their admission; most of them in a shorter time. The trephine was not used in any of the cases. On dissection there was found in eight of the cases fracture through the base of the skull, and in all of them laceration of the brain. There was only one case without urgent symptoms: here there was scalp wound, with fracture of parietal bone: slight exfoliation took place in this case, and the patient got well. In the other three cases there was concussion of the brain: these got well. One of the three cases was attended with more interest than the others, and I will relate it.

9th. James Hay, æt. 35, a sailor, was admitted on the 11th September, 1835. He had fallen from the mast of his vessel. He was insensible at the time of his admission. There was great tumefaction over the right temporal and part of the parietal bones. The right eye, and its surrounding cellular membrane, was much ecchymosed; the lower extremities were cold, and there was considerable hæmorrhage from the mouth: this was much increased by a cough which occasionally affected him: the pulse was very low and weak; he had not vomited. Warmth was applied to the extremities, leeches to the temples, and cold to the head. By speaking loudly to him he would rouse, but what he said was quite incoherent. This state of insensibility lasted four days, when he could be more easily roused, though little better understood. He frequently applied his hand to his right ear, and also to his side, which was examined, and the fourth rib was found to be fractured. On the fifth day he complained of pain in the right ear and temple, of numbness of the right side of the face; he had difficulty in putting out his tongue, and experienced difficulty in deglutition; this appeared to arise from pain. He had had a turpentine enema administered two or three times a day; leeches were daily applied to the head, and the cold had been continued. He had continued to part with blood from the mouth, until the fourth day, when he expectorated large quantities of pus. The tumefaction had now

nearly subsided, and a fracture, with slight depression of the upper part of the temporal and lower part of the parietal bones, was very perceptible; the ecchymosis had also subsided in the eyelid: the pupil of the right eye was found much dilated, that of the left contracted. On the application of light, there was not any action of the right pupil: the lid was paralysed. The expectoration of pus continued for a fortnight, and then ceased; the pain in the head gradually diminished, and the numbness of the face was very slight. He could swallow with ease; his memory was perfect, and he was perfectly sensible; the pupil remained dilated, and the lid remained paralysed. This was the state of the patient five weeks after the accident, at which time he was obliged to join his ship.

August 27, 1836.—It is now a year since the above accident took place, and on this day Hay called to see me: he had been a voyage to the East Indies. The depression of bone was more perceptible, and the right side of the head looked quite flat; the pupil of the right eye was much more dilated than the left, but acted freely on the application of light. There was still slight paralysis of the lid; he stated that he had had pain in the right side of the head, and in the right ear, particularly in changes of the weather; and occasionally the imperfection of the vision of the right eye was increased. These symptoms had gradually got less, and at this time he felt little or no inconvenience from the accident.

Out of the 34 cases of concussion of the brain, one died. In this case the symptoms rapidly ran on to those of compression. On examining the head, laceration of the anterior lobe of the brain was discovered.

In the two cases of popliteal aneurism which were operated on, the ligatures came away on the 16th and 18th days. In one of the cases the patient had been cured by an operation for popliteal aneurism on the opposite leg, fifteen months before. When he was admitted into the hospital the first time, it was thought that there was disease throughout the arterial system. He recovered well after both operations, and is again following his employment as an engineer.

The polypus uteri was excised; it

was very large; its neck was thicker than a man's thumb; there was not any hæmorrhage, and in a few days the woman left the hospital well.

Of the five cases of hernia, four were reduced; one (femoral) was operated on.

The scirrhus mamma was removed in December 1835. The whole breast was removed; the wound soon healed, and the patient left the hospital. A few days since she returned, complaining of the symptoms usually attendant on scirrhus pylori; she also complained of pain in some enlarged glands in the neighbourhood of the cicatrix.

In one of the cases of scirrhus mamma which was operated on last year, the woman returned in the course of eight months with jaundice; she complained of pain in the region of the liver, and of excessive debility. In two weeks after her admission she died. On dissection we found scirrhus liver, scirrhus mesentery, and the commencement of scirrhus uterus.

The twenty-nine cases that were operated on did well, with the exception of two; one of which was the case of amputation for traumatic delirium; the other was a man who was attacked with peritoneal inflammation after amputation.

CASE OF LATERAL DISLOCATION OF THE KNEE-JOINT.

To the Editor of the Medical Gazette.

SIR,
ENCLOSED I have forwarded the particulars of a case of lateral dislocation of the knee-joint, being rather an uncommon accident: I beg you will give it insertion at your earliest convenience. The man was a patient of Mr. Andrews, and being one of the house surgeons, the case came under my immediate notice.—I am, sir,

Your obedient servant,
J. B. SAMUEL.

Vauxhall, Sept. 27, 1836.

Henry Culpit, æt. 30, farrier, was riding a horse home from his employer's on the 22d last month, when the animal became restive, and in rearing, fell, the man being under: he was immediately brought to the London Hospital, when he was found to have sustained the above-named injury. The external condyle of the femur occupied the inner

articulating surface of the tibia, the other forming a considerable projection on the inner side of the knee; there was slight flexion of the leg, with eversion of the foot. Mr. Palmer and myself, the house surgeons for the week, by making extension and counter-extension, easily succeeded in reducing it. The limb was afterwards placed on pillows. It is almost unnecessary to add that it was followed by immense swelling of the joint, which required the repeated application of leeches, warm fomentations, &c., under the use of which it rapidly subsided. There was no constitutional disturbance.

ANALYSIS OF AN ANOMALOUS SPECIMEN OF DIABETIC URINE.

To the Editor of the Medical Gazette.

SIR,

SHOULD the following observations be considered worthy of notice, you will oblige me by inserting them in your Gazette.—I am, sir,

Your obedient servant,
G. O. REES.

59, Gullford-Street, Russell-Square,
Oct. 5, 1836.

A specimen of urine, supposed to be that of a diabetic patient, was lately sent me for examination by my friend Mr. Edinborough. On taking the specific gravity of the fluid, I was surprised to find that it was far *below* the healthy standard, being only 1008.

I was induced to make a particular examination of this specimen, in order to ascertain in which of the solid ingredients of the urine this deficiency occurred; or whether the low specific gravity was caused by a dilution of the secretion, while it retained its *solid* ingredients in normal proportion.

I subjoin the result of analysis, as procured from 1000 grains:—

Water	985.0
Urea	10.2
Extractive soluble in water, not soluble in alcohol—am- moniacal salts	0.9
Alkaline salts	3.5
Earthy ditto	0.4
Traces of lithic acid and vesical mucus.	

1000.0

The constitution of healthy urine may be represented by the same formula, as follows:—

Water	933.0
Urea	30.1
Extractive soluble in water, and extractive soluble in al- cohol and water—amino- niacal salts.....	18.9
Alkaline salts	16.0
Earthy salts	1.0
Lithic acid and vesical mucus..	1.0
	1000.0

It will be remarked on examining these analyses, that the diseased specimen is entirely wanting in the extractive soluble in alcohol and water, and that the extractive soluble in water only, is in very small proportion. The urea, if taken in relative quantity to the solid constituents of the diseased urine, will be seen to exceed by far the proportion which that principle bears to the quantity of solid matter in the healthy fluid. The proportion of alkaline salts, if taken in relation to the proportion of solid matter, will be nearly normal.

This diseased specimen is therefore to be regarded as a dilute urine, in which the urea has entirely supplied the place of the extractive soluble in alcohol and water; and, in part, that soluble in water only. The urea obtained during this examination was so pure, that it crystallized from the first alcoholic solution in perfectly white four-sided prisms.

The proportion of solid matter in healthy urine is 67 grs. in 1000 grs. 30.1 (or less than half) being urea. The solid matter of the diseased specimen under consideration forms 15 grs. only, in the 1000 grs., 10.2 (or more than two-thirds) being urea.

This diseased condition of urine is nearly allied to that mentioned by Dr. Prout in his work on the Urine, &c.; differing only in possessing a very light specific gravity. I am not aware that the entire absence of the extractive soluble in alcohol and water has ever, till now, been shewn in the analysis of diseased urine.

EXTRAORDINARY VERDICT OF A
CORONER'S JURY,

IN A CASE OF SUSPECTED POISONING.

To the Editor of the Medical Gazette.

SIR,

HAVING just perused the leading article in your number for the 13th instant, I am induced to send you the following account of an occurrence which came under my observation in this neighbourhood. If it possesses no other value, it will at least prove that there is urgent necessity for the community and the legislature to view with suspicion and distrust the published reports of coroners; and that it is incumbent on them to demand an increased efficiency from these persons, as well as the medical witnesses, in the discharge of their important duties.

On the 28th of last June a surgeon of this place was requested to accompany a medical man, to examine the body of a servant girl, 16 years of age, who had died under suspicious circumstances. The previous evening she retired to bed in perfect health and excellent spirits, about ten o'clock, after making a supper of boiled milk. She was said to have been unusually cheerful in the evening, and had been dancing. About twelve o'clock her mistress was disturbed by her moans, and noise produced by vomiting, and went to her assistance. She was vomiting, and appeared very faint, and said she suffered severe pain at the pit of the stomach. She was conveyed to a window, and being somewhat refreshed, back again to bed,—grew worse and worse, and died, *in the arms of her mistress*, about four o'clock, before medical assistance could be obtained. The stomach, with its contents, was removed; the former presented such decided characters of the effects of arsenic, that any one having an eye practised in the morbid appearances produced by this poison, would have drawn that conclusion; and this was declared by one who saw it, without any acquaintance with the history of the case. The tests for arsenic in the hands of these medical men,—the gentleman who made the cadaveric inspection, and two others to whom he had given portions of the contents of the stomach,—

were perfectly satisfactory. From the sulphuret of arsenic obtained, splendid coatings of the metal were procured, and from this, brilliant crystals of arsenious acid. From the quarter of a grain of arseniuret of copper I succeeded in deriving a sufficient number of crystals to form a conclusive opinion of the presence of the poison.

The fact of the presence of arsenic was made known by the surgeon before mentioned to the coroner,—a non-professional individual, but one who has long held the office,—who expressed great dissatisfaction to him on account of his having *presumed* to examine the body before the inquest had been held,—became extremely indignant,—asserted that he was liable to an action for daring, without *his* authority, to examine the body,—and so on.

At the inquest, this individual, from whose lips the coroner had heard, as a positive certainty, that the poor girl was destroyed by arsenic, was not called; and from the (I suppose) coroner's account, which appeared in the *Stamford Mercury*, which I shall extract, it is probable that the jury were kept in complete ignorance of it.

*Extract from the Stamford Mercury
of July 8, 1836.*

"On Thursday, the 30th ult., an inquest was held at Swinethorp, before R. Bunyan, gent., coroner, on the body of Sarah Maltby, aged 16, who died suddenly, on the Tuesday morning previous. It appeared that the deceased was servant to Mr. Bottomley, and had retired to rest in apparent good health. At about 12 o'clock she was seized with a violent pain in her stomach; her mistress got up, and took her to the window, and, after remaining there for some time, she somewhat recovered, and again retired to rest; but, about four o'clock in the morning, she was *found* dead in bed. Verdict — 'Died suddenly.'"

I shall not encroach upon your useful time, sir, by making any comment upon the inaccuracies of the *statement* of the circumstances which is placed before the public; the object is perceptible.—I am, sir,

Your obedient servant,

INDICATOR.

London, Aug. 20, 1836.

ANALYSES AND NOTICES OF BOOKS.

“L'Auteur ne tue à allonger ce que le lecteur se tue à abrégé.”—D'ALEMBERT.

The Botanist; containing accurately coloured Figures of tender and hardy Ornamental Plants, with Descriptions. Conducted by B. MAUND, F.L.S., assisted by Professor HEN-SLOW. 4to. To be continued Monthly. No. I.

SINCE botany, which, as some are of opinion, never should have been divorced from medicine, of which it has been aptly styled “the hand-maid,” has been again included in the curriculum of medical education in this country, various works have appeared, calculated to assist the student in acquiring a knowledge of the principles of the science. Something was still wanting, which, by appealing to the corporeal as well as the mental eye, should take captive, as it were, two senses at once, and so ensure the entrance of knowledge by two loopholes. A work with pictorial illustrations could alone do this. Such a one appears likely to be supplied by that of which we have copied the title above. A good introductory notice explains the nature of the assistance it is calculated to afford; the plates are well engraved, and most exquisitely coloured, while the descriptive letter-press conveys much scientific and popular information respecting the plants delineated. The great peculiarity of this work seems to be, that the objects figured are not, as in other works, regarded as isolated individuals, but as members of the vegetable kingdom, having affinities to other individuals. It therefore leads to the consideration of the principles of the natural method of botany, and induces the reader to take comprehensive views of the plants which come before him, in respect to their organization and physiology. On this account, medical students are likely to feel more interested in it, and it will constitute a valuable companion for them, when pursuing their studies, and a pleasing manual to refer to when settled in practice, and reading, as many will be, if not altogether in the country, at least in houses with gardens attached, where, during their hours of leisure, they may

enjoy a delightful recreation in the cultivation of many of the elegant productions of nature, of which they might, perhaps, never have heard, but for such a work as this; the cheapness of which puts it within the reach of every one. To such of our readers as already possess a taste for botany, no further recommendation is necessary; while, for those who are yet unacquainted with it, we do not know any work better calculated to inspire a love for it, and gratify it when awakened.

MEDICAL GAZETTE.

Saturday, October 8, 1836.

“Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso.”

CICERO.

HOMŒOPATHY AND ITS LATE DOINGS.

THE death of Malibran, lamented as it is by the community at large, and as it must be by a great portion of the civilized world, has proved, it would seem, rather a God-send to a small knot of ignorant but mischievous pretenders: men by whom any kind of notice, even though originating in a calamity itself, must be esteemed as a positive benefit. The disaster to which we regret to have to allude has conferred a transient notoriety, however unenviable, on the *homœopathic* practices; and it was a mere chance that it did not do more. Homœopathy wanted but another step to put it on a footing with the *hygeian* quackery—the publicity of a coroner's inquest; a distinction which it had just now nearly obtained.

We do not mean to impugn the judgment of those gentlemen—the committee at Manchester—who decided that an inquest in Madame Malibran's case would have been improper, or might fairly be dispensed with. But we object to such a decision in the abstract:

strict justice would demand, that if the Morisonian manslaughters be exposed and punished as they deserve, the Hahnemannian doings, which also deal insidiously and destructively with human life, should certainly not be screened.

Some gentle reader may, perhaps, suppose that we are too severe on the disciples of Hahnemann: that, at the worst, they are but harmless quacks; and that their doses being infinitely small, are capable, accordingly, of doing infinitely little mischief. We deny the inference, and must insist on the correctness of our principle. The doses, we will suppose for argument sake, are in themselves perfectly innocuous; yet such doses, when given at a moment when energetic practice is required, are fraught with danger; and when an ignorant practitioner, professing homœopathy, rashly takes upon him the responsibility of a critical case, flinging away the moments that are most precious, and on the right employment of which the balance of life or death turns, we say that such a practitioner is guilty of a great crime, and merits the sternest visitation of the law. In acute disease, and cases similar to that of the unfortunate Malibran, the *expecting* practice, as it has been called, or the "leaving all to nature"—even if homœopathy were as harmless as that—were to throw overboard our helm, sheet anchor, and all that might contribute to our safety, and to trust to the mercies of a providence that ever frowns on the inactive.

In the most stupidly savage state of society, nothing more barbarous could be done. When the means of depletion, or lowering the system, on the one hand, or those of stimulating it, on the other, offer the only hope of preservation, homœopathy—taking even the most favourable view of it—sits still and does nothing,—while it promises as much as, nay, more than, if the rules of art, de-

rived from the soundest experience, were duly put in practice.

But homœopathy does not even possess this negative quality on which to rest its defence. It plays upon the imagination of its dupes: it works upon them by certain pretended latent affinities, as Mesmerism used to do in the golden days of animal magnetism: and in this employment of a powerful instrument, for good or evil, it but too often operates mischievously on susceptible constitutions. It may happen, by its intrinsic inertness, to do no harm, but the chances are almost wholly against such a result.

Here, then, is a system, pretending to belong to medicine, to be itself medicine re-organized and reformed—yet playing in the dark, practising secretly, and now and then vaunting of the ineffable virtues of imperceptible particles of matter. How long is medical science, extended and enlightened as it has been of late years, to afford the passport of its name to audacious adventurers thus using it for the vilest purposes? And will a community, ever professing to enjoy the benefits of diffused information, always remain blind to such palpable fraud?

It will, no doubt, be said by some of the brazen impostors who support the scheme, that all this is set forth in ignorance: that Hahnemannism has not got fair play: that prejudice is strong against it, and it has never obtained a trial. This is all false: the system (system!) is perfectly well known as far as it is intelligible: its principles (!) are as thoroughly understood by the generality of well-informed medical men, as by the homœopaths themselves: but what is better still, the fruits of the system, as they occasionally come before the public, are closely observed and appreciated. Dare they deny, too, that they have had fair trial—when, not to

speak of others, Andral, in the largest and best appointed hospital in the French metropolis, afforded every opportunity to the cleverest of the homœopaths, and found that they failed to make good their pretensions?

But what right have they, we would ask, to claim such an indulgence? What have they done to entitle them to so much confidence as to have the lives of patients committed to them for experiment? Let them give us the guarantee of even one physician of eminence, who will assure us that we can conscientiously trust to Hahnemannism in any one case. They have no such surety to offer. Yet here have these medical St. Simonians been for years endeavouring to make a stand, and have produced, after all, nothing better than their Belluomini (by importation), and their Quin: we had almost forgotten—their Uwins, save the mark! When we inquire for their literature, —their knights of the pen— we find their champion in the person of a worthy son of the church, whose talent for invective and the misapplication of texts of scripture, forms his chief claim to public attention. We have had a specimen of him, and can truly say that we congratulate Hahnemannism on the possession of such a mild, meek, discreet, and sagacious partisan. There have been others also, who, like Dr. Uwins, have favoured the world with a silly pamphlet, or a set of apocryphal cases, from time to time; but they have all long since gone down the channel into the *sentina* of oblivion!

And these are the creatures that talk of the envy and prejudice of the medical profession, and who call for a fair trial. It is likely they will have this; perhaps sooner than they could wish. Let them only get possession of another case like the recent one—let the treatment be, as much as possible, like that applied to the unfortunate

Malibran—let the remedies be kept secret, and the assistance of eminent practitioners be declined—let only this be done—the catastrophe will be certain, —and we shall warrant them publicity enough. The public will have a right to learn then, who are they that, under the guise of authorized practitioners, tamper with the lives of the liege subjects; and the *coroner* will take care to investigate the matter fully. Nor will it serve the turn of those who may then shrink from the consequences of their doings, to induce the nearest relative of the deceased to quit the kingdom, and to enjoin that the body shall not be meddled with—save for the purpose of burying it with all privacy and despatch. Such things as these cannot again occur. Homœopathy must have a trial; it must have, it has a right to have, the same publicity and attention as has been bestowed on its rival system—that of Morison.

Since the preceding remarks were written, a letter from M. Belluomini, the homœopath who attended Madame Malibran in her fatal illness, has appeared in the newspapers. The *Doctor*, among other weak and silly things, says, that after a careful examination, he found that “the viscera of the chest and abdomen had not been attacked with malady,”—and yet that “the first effect of the medicines was to allay the cough a little;” and again, that “some hours after, the fever increased, and the cough and delirium returned.” We should infer from his account (and unfortunately we have no other) that the ill-fated lady had inflammation of the chest, and was suffered to die *homœopathically*. Dr. B., we should further observe, carefully concealing his treatment, says, “I immediately set to work to administer to the patient *those remedies which I thought desirable* :” but not a word as to *what* they

were. He did not wish to meet the highly respectable medical men previously in attendance: "I do not think it necessary," was his answer on being asked to do so! So much for homœopathy, and its fair and open dealings.

AMOUNT OF FEES AT DIFFERENT MEDICAL SCHOOLS.

FROM the note which follows, it will be seen that some gentlemen have misunderstood the table of fees inserted at page 26 of our last number. We did not compare the amount charged at different schools for the shortest period which will enable a pupil to apply for examination at the College of Surgeons or Society of Apothecaries, but our calculation referred to unlimited attendance, because we knew that the great majority of pupils take perpetual tickets for most of the courses, viz. Anatomy, Medicine, Surgery, and Midwifery; and we therefore thought that the most useful table to them would be one showing the expense of unlimited attendance on all the lectures entering into the curricula of the Corporate Bodies. But if, instead of taking perpetual tickets, they confine themselves to the courses absolutely required, then the amount will be somewhat less than in our table. Thus, as stated by Mr. Bayntin, at St. Bartholomew's Hospital, it becomes reduced to 57*l.* 15*s.*; and we may add, that at Guy's the reduction is to 56*l.* 14*s.*; at London Hospital, to 50*l.*; at St. George's, to 49 guineas; the Aldersgate School, 35 guineas, &c. &c.

Our object was to refute the misrepresentations in the *Lancet*, as to the alleged cheapness of University College, which we demonstrated unanswerably to be by much the dearest school in London. According to the present calculation (*i. e.* of the expense of those lectures merely which the corporate bodies require), the amount is

not less than 67*l.* 12*s.* to pupils who have not a nomination, and 63*l.* 2*s.* to those who have. But for Mr. Wakley's advocacy, this disparity might have escaped notice: so much for having an indiscreet friend!

To the Editor of the Medical Gazette.

SIR,

In the tabular view of the Amount of Fees at the different Schools for attendance on the Lectures required by the College of Surgeons and Society of Apothecaries, you have stated the amount of fees at the Medical School of St. Bartholomew's Hospital to be 65*l.* 2*s.*; whereas by the Prospectus of the School it appears that the total expense for the above purposes is 57*l.* 15*s.*

As this inaccuracy is likely to mislead, I write to request that you will correct it in your next number.—I am, sir,

Your obedient servant,

W. J. BAYNTIN,
Curator of the Museum.

St. Bartholomew's Hospital,
Oct. 6, 1836.

ACCIDENTS IN MINES,

FROM EXPLOSIONS OF FIRE DAMP.

THE public attention is ever and anon painfully called to this subject; yet it is surprising with how little effect. No steps are taken by government for affording protection from the frequent loss of life which occurs in the coal districts, nor do the mine-owners profit in the least by the sad experience they obtain so constantly, of the inefficient means which they have hitherto employed for preventing accidents. Only last week a fresh explosion of fire-damp destroyed eleven persons, at Newcastle-under-Line, where the work was being carried on with common candles: the verdict of the coroner's jury was, "Accidental death." How that can be called *accident*, of which the probabilities are so manifest, is to us an enigma.

It is nearly a year since we made some remarks on this subject, suggesting that a regularly organized board of visitors, or commissioners, appointed at the Home Office, should superintend the safety of the mining districts; and we insisted on the speedy adoption of those lamps which had been proved to be perfectly secure. The government has re-

remained supine in the matter, notwithstanding the strong representations contained in the Report of the Parliamentary Committee: but we are glad to find that a proper spirit has begun to prevail, touching the necessity of guarding more effectually against the explosive gases met with in the collieries. The insecurity of the Davy-lamp in *currents of inflammable air* (the very emergency in which its services would be most needed), has been demonstrated to the conviction even of the most incredulous; and the superior merits of that lamp which stood every test and ordeal to which it was submitted, in presence of the Parliamentary Committee—we mean that of Messrs. Upton and Roberts—are now almost universally acknowledged.

We have derived much satisfaction from the perusal of the subjoined letter from Dr. Fife, of Newcastle: it will be recollected that this gentleman, last year, wrote a pamphlet on the fatal accident which had shortly before occurred at Walsall, and by which above 100 lives were lost in a moment*. Among the preventives which he then suggested, the construction of *perfect* Davy-lamps was dwelt on as of paramount importance. Dr. Fife, at that time, implicitly believed in the perfection of the Davy, if it were only properly made and duly attended to. He even challenged the statement of any well-authenticated case tending to invalidate his opinion. Let us now see his present impressions as expressed in the following letter to the Editor of the Newcastle Journal. We have only to add, that we think the Doctor's candour does him great credit:—

In reading the *Courant* of the 3d inst., my attention was arrested by the subjoined passage in the report of the "Natural History Society," read at its seventh anniversary meeting. The report concluded by enumerating the papers which had been read at the several meetings during the year, and the investigation which had been made of the *Mining Gas* in this district, in consequence of its having been alleged to be of so highly explosive a nature as that the Davy Lamp was not a sufficient protection against it. The result of the examination was, "that no free hydrogen was found, or any other highly explosive gas, against which the lamp in question was not a sufficient protection." To the last sentence of the above extract I

shall at present confine myself. As to the constitution and properties of the gas met with in our mines, I believe these were perfectly analysed and as thoroughly understood by the illustrious Davy as by any modern chemist; consequently the non-existence of free hydrogen cannot be regarded as a new discovery. Again, as to the high or low explosive power of any gas of our mines, I believe he was also fully aware that the explosive or detonating power existed only when such gas was diluted to a certain point with atmospheric air, and that when the dilution was either above or below such point, that eminent man knew, though inflammable, the mixture would not explode. He was also aware that a certain degree of atmospheric pressure was essential to detonation. I come now to the most important part of the extract, viz. the assertion "that no gas existed in mines against which the Davy Lamp was not a sufficient protection." Had this statement been made prior to the publication of the evidence taken and the experiments made before the parliamentary committee "on accidents in mines," I should have been less surprised; as it is, I am at a loss to conceive upon what grounds any scientific body could advance such a statement, as the *fallacy* of the Davy Lamp is by that evidence and those experiments fully established. At the time of the parliamentary investigation, no one could believe more firmly in the security of the Davy Lamp than I did; I am now, however, not only from the testimony of *practical miners* and the experiments of scientific chemists, but also from the repetition of those experiments myself, fully convinced of my error, and conceive it to be my duty to endeavour to correct the propagation of an unfounded assertion, the only tendency of which would be to give unwarrantable confidence to the miner, and possibly lead to farther sacrifice of valuable lives.

GEORGE FIFE, M.D.

Eldon-Square, Sept. 15, 1836.

PROJECTED POOR LAW CLUB AT CAMBERWELL.

To the Editor of the Medical Gazette.

SIR,

FROM the great impartiality with which your journal is conducted, I am induced to send you a few lines respecting the medical club intended to be formed in the parish of Camberwell.

According to the Poor Law Amendment Act, no further medical relief will be given

* See MEDICAL GAZETTE, vol. xvii. p. 146.

to the poor of this parish after the 25th of March next, (except in the workhouse): to avert the evils of such a measure, it was recommended by the Board of Guardians, that an independent medical club be formed to attend the poorer classes, for such small sums as they, with the annual subscriptions, might be able to afford. With this object in view, a meeting of the resident practitioners was called, in order to make rules for carrying it into effect, and to divide the parish into districts, leaving the poor the option of selecting any one of the medical men of the district to attend them, upon subscribing a small sum to the club, which sum was to be paid whether ill or well, the scale of charges varying according to the number of the family. Judge, then, of the surprise, not to say indignation, of the resident medical practitioners who were favourable to the measure, upon entering the room, to find it occupied almost entirely by medical men collected from different parts, the majority having no connexion whatever with Camberwell, and whose avowed object was a determination, as one of them expressed it, to crush the measure; applying to those who were willing to lend their support, terms of no measured censure, and making up by clamour what they were deficient in argument; in fact there was not a single argument against the principle; the only word that could be heard 'ever and anon' above the *din and confusion* that prevailed, were *black sheep, degrading, lowering the dignity and honour of the profession*; and some gentleman went so far as to talk of posting the names of all who were favourable to the measure; no doubt, in order that "we petty men should walk under his huge legs to find ourselves dishonourable graves," and with a view that we might be denounced by our brother practitioners. After witnessing such a scene as this, pray spare us from hearing any more of the cant about the liberality and honour of the profession. In conclusion, allow me to transmit the names of those who "(to their praise be it spoken)" are willing to lend their assistance to the much abused medical club.

Practitioners favourable to the forming of the Club.

Mr. Bean, Mr. Wm. Bean, Mr. Tobias Browne, Mr. John Browne, Mr. Forbes, Mr. Flower, Mr. Hughes, Mr. King, and Mr. Young.

Unfavourable.

Mr. Bowen, Mr. Bristowe, Mr. Massey, and Mr. Scrimshire.

It is proper to state that I confine myself to the *Camberwell district*, leaving out the *Peckham* and *Dulwich districts*; also

the *Walworth, Blackfriars' Road, London Road, Kent Road, Trinity Street, Union Street, Blackman Street, and Newington*, thinking it absurd to suppose that any of the medical men residing in the omitted districts would be appointed to attend the *Camberwell district*.

In order to guard against any misapprehension, I beg to observe that the names stated as favourable, are those given in to the Guardians, as fully agreeing to the principle; and it was their intention to have made some required alterations in the scale of remuneration, as well as to have excluded domestic servants in situation, and to have reduced the scale of eligible members, from those receiving 35s. a week down to 25s. Other alterations, especially that regarding midwifery cases, were in contemplation to be proposed at the very meeting when the operation of *crushing* was so powerfully applied to the system by the practitioners of *Walworth* and neighbourhood.

After this plain statement, I confess that notwithstanding all that has yet been said or written on the subject, I cannot see why the medical men of *Camberwell* should allow themselves to be dictated to by those in no way connected with the *Camberwell district*, and suffer them to decide the question whether it is expedient to form a *Medical Club* or not. I trust the medical men of *Camberwell* will assert their independence by deciding this question for themselves.

By inserting these remarks, you will greatly oblige

A CAMBERWELL PRACTITIONER.

Oct. 3, 1836.

NEW FARTHING CLUB; OR METROPOLITAN INFINITESIMAL DISPENSARY.

(From the *Medico-Chirurgical Review*.)

A prospectus of this important institution has just reached us. It is to be under the direct patronage of a Prince of the Blood, a distinguished EARL, and many of the nobility and gentry. Its own merits, however, will insure it universal approbation and support. The superintendence of the Dispensary is placed in the hands of four of the most experienced HOMCEPATHISTS of this country. It is on a plan so much superior to the penny-clubs now spreading over the country, that it will soon supersede them all. The subscription is to be only *one farthing* per head per annum! We may calculate that, taking the rich with the poor, there is an expenditure, in London, of twenty shillings per

head, on medical attendance and medicines—and as the Metropolitan Dispensary will do away entirely with the heavy fees and long bill of physicians, surgeons, (excepting for operations), apothecaries, and chemists, the saving to the public of this capital will be more than a MILLION ANNUALLY!!

There can be no doubt that the whole population will subscribe at once; but, under such patronage, a charter of incorporation will certainly be obtained next session, and thus its success will be secure.

Four homœopathic laboratories are to be established, namely, at the Chelsea Water Works, on Primrose Hill—at the New River Head—at South Lambeth—and at Hampstead. From these sources infinitesimal doses of the choicest homœopathic remedies will be daily issued, not only for the cure, but for the prevention of all diseases. Thus it is calculated that, when scarlatina breaks out, a daily solution of twenty grains of belladonna in the Chelsea reservoir, will protect all individuals (within the range of that company) against the scarlet fever, besides curing those who have actually caught the disease. If cholera re-appears, a lump of camphor is to be thrown into each of the four reservoirs, the emanations from which will soon check the Asiatic pestilence*.

The great beauty of the infinitesimal system is this, that each remedy will only grapple with, or prevent, those diseases that are of its own nature — “SIMILIA SIMILIBUS CURANTUR.” Thus a few grains of aconite daily dissolved in each of the reservoirs, will cure or prevent all the aconite diseases of this overgrown metropolis, without producing any effect on those in health, or modifying any other diseases or remedies.

The saving of money will be the smallest part of the benefits which must flow from this most fortunate discovery. In a few years, all diseases, excepting those resulting from casualties, will disappear, or nearly so, and the value of life will be so enhanced, that the insurance offices will be able to reduce their premiums nearly one-half! The grief, anxiety, and sorrow of families, for the loss of children, &c. will be prevented, as all people will then die the death of Nature, far beyond the obsolete boundary of three-score years and ten.

It is true, however, that there is no un-mixed good in this world. Certain orders of society, now flourishing, will be reduced to beggary. The Apothecaries' Company (who are getting up a petition

to parliament against homœopathy) will be ruined by the “atomic doses” of the Infinitesimal Dispensary. The College of Physicians, being ruined already, thinks it useless to remonstrate. The College of Surgeons, though they will still have the monopoly of operations, are preparing, nevertheless, to petition the legislature, because they well know that, though surgery is their *profession*, physic is the best part of their *practice*. The apothecaries may, of course, shut up shop—and all those drug-palaces, whose windows, at night, look like constellations of ethereal fire—

“*flammasque imitante pyropo*”—

must be converted into gin-shops or soda-water manufactories. It is to be hoped that government may, in charity, grant a free passage to Australia for, at least, twenty thousand ALLOPATHICS, who will thus be thrown out of work in this metropolis.

These are little specks of evil attendant on a public—a universal blessing. The homœopathic superintendants have humanely determined to station one of their élèves, with a few small vials and pots, some miles beyond Oxford, in order to medicate the stream of the Thames, for the benefit of the University, Maidenhead, Windsor, Kingston, Richmond, and the various towns along the river as far as Gravesend. It is calculated that a scruple of oxymuriate of mercury, and three pints of fluid extract of sarsaparilla, thrown into the Thames at Fulham, will prove a powerful alterative for all those who drink the water supplied by the Chelsea and South Lambeth Companies. A much smaller quantity will do for the New River Head. Infinitesimal Dispensaries will, without doubt, be established in all the great cities and towns of England. And, as the present race of practitioners will certainly be the last of their kind, so our great medical schools, and even our hospitals, will shortly vanish from the scene. Homœopathic doses of medicine will naturally require but “atomic doses” of the science on which medicine depends. Indeed, we see no reason why, on the homœopathic system, we should undergo the drudgery of studying anatomy, physiology, therapœia, or chemistry. A very few medicaments, divided and subdivided into inappreciable tenuity, are endued with the power of penetrating the most minute tissues of the human fabric—with the instinctive sagacity—the more than chemical affinity, of searching out, seizing, and coalescing with their “SIMILITUDES” in these remote recesses,—and there neutralizing their morbid qualities, and expelling them ultimately from the body! If this be not the millennium of medicine,

* See Dr. Uwins's pamphlet.

we can form no idea of what a millennium is! HOMŒOPATHY has, we conceive, brought us to the verge of this happy epoch; and the infinitesimal physician is entitled to the infinite gratitude of mankind!

P.S.—We have just learnt a piece of curious information. It is this: Ever since the new Poor Law Act came into operation, a celebrated homœopathist of this metropolis has been giving lectures on the infinitesimal art, to pupils who have “passed the Hall,” and who are qualifying for the office of “contract doctors” throughout the provincial districts. We have now a solution of the low rates at which these UNDERTAKERS contract to attend the sick poor. The homœopathic system will enable these practitioners to beat the ALLOPATHICS clean out of the field! The training requires about six weeks, and the whole apparatus medicaminum consists of a few bottles of medicated mustard seed, labelled “homœopathic pills.” Our informant shewed us a single formula, and the *mode* of preparation is the same in all. Five grains of extract of aconite are dissolved in a pint of distilled water, and the solution is poured off clear. Into this is put a pint of white mustard seed. In a few hours the seeds swell and absorb the whole of the solution. They are then spread out in the open air, when they soon shrink back to their original dimensions, being, however, impregnated with the aconite, and fit for use. The dose is from 1 to 10 of these aconite pills. The mustard seed is medicated or imbued with all other articles of the homœopathic pharmacopœia in the same way. The cost of physicking a large parish on the “atomic plan,” will, it is supposed, not exceed half a crown per annum.

CHEAP PHYSIC AT AYLESBURY.

To the Editor of the Medical Gazette.

SIR,
IN the MEDICAL GAZETTE of the 10th inst. I perceive a letter of a correspondent who signs himself “An Observer,” and who affects disgust with my circular of terms; but Sufferer, I conceive, would have been a more appropriate cognomen. Permit me, Mr. Editor, to observe, had the writer been a *mere* observer, and actuated by impartial feelings, he would have preceded his sarcasm by a candid avowal of the degraded state of the profession, in this quarter long ere the “Hand Bill” appeared. In my opinion, the base motive of revenge, or self-interest, prompted the “Observer” to attack me *individually*, and allow others to pass with impunity,

who had lessened the independence of the profession far more than I have. As an instance, I transcribe the following from the parish minute book:—

“We engage to attend the poor of Aylesbury in the town, and all adjacent towns and villages within ten miles, in every case of sickness and surgery—to furnish trusses, bandages, and leeches—to include all the midwifery cases—and to return any money for attendance on extra paupers, or fee due to us for attendance on coroners’ inquests, for the sum of forty pounds, from April 10, 1835, to April 10, 1836, payable by equal quarterly payments.

(Signed) — & —, Surgeons.

The population of Aylesbury consists of 5000 inhabitants, and the pauperized state of this county is well known; the reader will therefore readily perceive that the above paltry stipend is infinitely less lucrative than *my* system of charges.

I remain, sir,

Yours respectfully,

J. A. MARSHAL.

Aylesbury, Sept. 27, 1836.

REGISTRATION OF BIRTHS AND DEATHS.

To the Editor of the Medical Gazette.

SIR,
It is a well-known fact, that, from the total want of accurate information regarding the causes of deaths in this country, the science of medical statistics is retarded in its progress. It is therefore extraordinary, that now an opportunity is offered to the medical profession to ensure the most accurate reports, by taking the registration into their own hands, they should, (as has in many instances been the case) refuse to fulfil the duties of registrars under the new act. The refusal must arise either from the apprehension that the trouble would far exceed the remuneration, or from not having considered the important aid it is now in our power to give to science. If the former be the objection, it has probably been overlooked, that no person can obtain burial without the registrar’s certificate. This will ensure him immediate information of every death, without having to seek for it; and in the case of births, children unregistered within six months will not be legal inheritors of property. There can, therefore, be no doubt of the registrar having *notice* of all births, save those, perhaps, of the absolute pauper, and of them intelligence can be readily obtained from the relieving officer of the district. In the latter case, were the registration in the hands of our pro-

session, the following facts, important to the public health, might be established.

The number of deaths by diseases known to attend particular professions and trades.

The number, and nature, of the fatal diseases of particular districts or localities, in comparison with other districts.

The rare fatality of some, and the frequent fatality of other, maladies.

In any given population.

The remuneration (payable from the Board of Guardians) is 2s. 6d. each for the first twenty entries in every year, and 1s. each for every succeeding entry, with an additional 5s. for the registration of every birth of which the registrar has not had notice within forty-two days.

But it ought not to be considered in a pecuniary point of view, so much as a means of advancing medical science.

In foreign states, where the registration of births and deaths is chiefly confined to medical men, the most beneficial results are known to ensue, while, as I have before said, our statistics are notoriously deficient.—I am, sir,

Your obedient servant,

T. G.

September 28, 1836.

CASE OF ANEURISM OF THE THORACIC DUCT.

By DR. ALBERS, of Bonn.

THE patient, a man of fifty-one, died of abscess of the liver. On examining the body after death, Dr. Albers found, in the region of the solar plexus, amongst several hard cartilaginous tumors, an elastic soft one, with a half-transparent tegument. It was knotty, and about the shape of a fig. At first he took it for an hydatid; but it was soon discovered that it was bound by membranous bands in several places, and that a canal led into it, both above and below. It contained a quantity of fluid lymph, in which flaky matter was suspended. The internal surface of the tumor was smooth and uniform. A sound could be passed up the canal, both superiorly and inferiorly. In the latter direction its course was followed, and it soon became evident that the tumor was an aneurism of the thoracic duct. Its parietes were thicker and firmer than those where the duct had not lost its normal calibre.

Dr. Albers has only seen one similar case, viz. a dilatation of the cisterna chyli, found at the examination of a dropsical patient.

It is singular that the thoracic duct is not oftener affected by the diseases of

surrounding organs. How often it is compressed in the scrofulous and consumptive, by enlarged glands, tumors, &c.! But these compressions are not attended by corresponding dilatations, as is the case with arteries and veins. Dr. A. has seen a case in which the thoracic duct, in the middle of its course, had been reduced by pressure to such a small calibre, that it would not admit even a bristle. In another case the canal was altogether obliterated; but in neither was the calibre of the canal below the narrowed part altered by the compression. (See also Rokitsanski, *Austrian Annals*, vol. xvii. p. 411.) The cause of this absence of dilatation in cases of compression lies, doubtless, in the nature of the fluid, in the weakness of its current, and also in the fact that there must be more branches of the thoracic duct anastomosing with the venous system than is generally supposed. A proof of this is, that in children in whom the calibre of the duct has been materially narrowed, no emaciation has followed in consequence. Wutzur has discovered a branch of the thoracic duct leading into the vena azygos. The most frequent cases of dilatation of lymphatic vessels are those in which they contain tuberculous, scrofulous, and cancerous matters. Numerous descriptions of such cases are found in the works of Cruveilhier and Carswell.—*Hannoversche Annalen*, and *British and Foreign Medical Review*.

NEW METHOD OF PRESERVING DEAD BODIES.

By DR. TRANCHINA, of Palermo.

THE results of this method were first published in the Sicilian journal *La Cerere*, in May, 1834; but the actual process was first made known and openly practised by the author, on the 11th May, 1835, in the military hospital, *Della Trinità*, at Naples. The operation consists in the injection of the body, through the carotid artery, with a solution or mixture of two pounds of arsenic in twenty or twenty-four pounds of water, or spirit of wine, coloured with a little red lead or cinnabar; and in the introducing, by means of a trocar, into the abdominal cavity, the same solution, in cases where putrefaction had made some progress. In some cases it appears also that the solution is injected into the anus, nostrils, &c. By this process the body is kept fresh, flexible, without smell, and of its natural colour, during more than two months; after which it gradually dries, hardens, becomes of a darker colour, and can be preserved for years. For this discovery, the great importance of which is self-evident, and for its public disclosure, Dr. Tranchina has been presented, by the

King of Naples, with the sum of 3000 ducats, has been raised to the dignity of knight of the order of Francis I., and appointed military surgeon of the second class.—*British and Foreign Medical Review*, Oct. 1836.

CHARING-CROSS HOSPITAL.

A MEETING was held in Great Windmill Street, on Monday, for the ostensible purpose of expressing the opinion of the medical public with regard to the recent transactions at the Charing-Cross Hospital. The chair was taken by Dr. Birkbeck, but he was not supported by any such numbers, or by such members of the profession, as to give weight to the proceedings. Resolutions were passed condemnatory of the plan on which the hospital is conducted, and much disapprobation expressed of Mr. Howship's conduct in giving Mr. Pettigrew 500/.; but we are not aware of any censure having been passed on the latter for accepting it.

We quite agree with the resolution declaring the office of "Director" an absurdity, but the time and manner in which public attention has been directed to the subject give it all the air of private pique. We cannot compliment any of the parties on the figure they make, and would advise them not to intrude themselves upon the public unless they have something to adduce much more to the point than any thing which has yet appeared.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

September 29, 1836.

- William Ralph Peck, Kimbolton.
- Edward George Baron, Hull.
- John Dickinson, Plunder Bridge.
- Henry Richard Smith, Newark.
- Robert Norton, Nailsworth, Gloucestershire.
- Robert Baget, Shrewsbury.
- Joseph Glover, York.
- Frederick Hanham, Bath.
- William James Clark, Skipton Bridge, Yorkshire.
- Richard Ley, Newton Abbott.
- Richard Thomas Morris, near Wigan, Lancashire.
- William Foster, Royal Navy, Yarm.
- Robert Fothergill, Bedale, Yorkshire.
- Charles Bruorton, Salisbury, Wilts.
- George Eveleigh.
- Mathew Moorhouse, Holmfirth, Yorkshire.
- William Marsden, Thornhill.
- Frederick Heald, Wakefield.
- James Naylor, Preston, Lancashire.
- Joseph Parkin, Workington, Cumberland.
- Charles Frederick Jenkins, Thames Ditton.
- Allen Joseph Taylor, Morpeth, Northumberland.
- Thomas Wright, Wolverhampton.
- Henry Poole Palmer, Winterbourne, Bristol.
- Alexander Wright, Birmingham.
- James Cowherd, Kendal.
- Thomas Truran, Exeter.
- William Field, Tong.
- Francis Harold Duncombe Lewis, London.
- Thomas Mackenzie Smith, Bideford, Devon.
- James Barton Nottage, Lancaster.

Tuesday . 4	80 53	29·41 29·51
Wednesday 5	82 55	29·72 29·83

Prevailing Winds, W. by S. and N.W.
Except the 2d, 4th, and 5th, generally cloudy, with frequent rain.
Rain fallen, 1 inch, and ·825 of an inch.

CHARLES HENRY ADAMS.

NOTICES.

INTRODUCTORY LECTURES.—We really cannot make room for "Introductory Lectures." Such addresses we presume to have been heard by the only parties to whom they can be useful;—we mean the pupils at the several schools: for others they do not possess sufficient interest to warrant us in giving them insertion.
MR. WALKER's reply has been received.

WILSON & SON, Printers, 57, Skinner-St. London.

LECTURES

ON

FORENSIC MEDICINE;

delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE III.

Age, medico-legally considered—Mode of ascertaining the Age from Physical Appearance—Age of the Fetus—Growth of the young—Periods of Human Life—Infancy.

The first subject of a special nature to which I shall call your attention, is Age.

The consideration of age is an element in almost every investigation undertaken by the medical jurist. Whether his inquiries are relative to the living or the dead—whether his object be to ascertain the identity of an individual, or to appreciate the extent and nature of personal injuries—whether his researches bear on questions of abortion, pregnancy, parturition, sterility, in all these, and a number of other cases, which I need not stay to enumerate, as you will be better prepared to appreciate their importance hereafter, age is to be duly considered.

Legal distinctions respecting Age.—Our law is precise regarding certain epochs of life: there are certain ages to which particular rights and responsibilities are assigned. A male at twelve years old may be sworn to the oath of allegiance; at fourteen he attains years of discretion; may consent or dissent to marriage, may choose his guardian, and make a valid will of his personal property; at seventeen he may be an executor; at twenty-one is at his own disposal, and has perfect power to do as he pleases with his estate, both personal and real. A female at seven may be betrothed or given in marriage; at nine she is entitled to a dowry; at twelve is at years of maturity,

and therefore may consent or disagree to marriage; if proved to have sufficient discretion, she may at this age also bequeath her personal estate: at fourteen she is at years of legal discretion, and may choose her guardian; at seventeen may be an executrix; and at twenty-one may dispose of herself and lands. Again, with respect to criminal liabilities and immunities, a person under twenty-one (being in the eye of the law an Infant) is privileged as to common misdemeanors, so as to escape fine, imprisonment, and the like: in the case, however, of any notorious breach of the peace, such as riot or battery, he is liable to suffer the prescribed penalties, if he be above fourteen. A felonious crime still further abridges the privilege of age: for infants of ten have been hanged for murder—the evidence of malice having been clearly made out: and it is only under the age of seven that a person cannot be guilty of felony; for then it is considered that a felonious discretion is almost an impossibility in nature.

In all such cases, where there is no documentary evidence of age to produce—a circumstance far from uncommon in a country like this, so negligent hitherto in respect to registries of birth, and even of baptism—there is obviously no other resource than to ascertain the fact by reference to physical peculiarities. And here the assistance of the medical jurist is required.

Other occasions of inquiry as to Age.—Among the qualifications and disqualifications for military and naval service, age forms a special object of inquiry. It is a highly important element in the selection of recruits; and we even find twenty fixed as a minimum, in a late order from the Horse Guards, relative to recruiting for service in tropical climates. Mr. Marshall justly observes on the subject, that “as the exact age of men in this country cannot commonly be easily or satisfactorily ascertained, the surgeon who inspects a recruit should be

authorized to estimate the age by physical appearances."

In effecting *policies of Life assurance*, I need scarcely remind you that much depends on the age of the insuring party, the premium being almost wholly regulated with reference to that point; and it may be your duty, as medical officers either of the company or the applicant, to take care that there be no error or fraud committed in this respect.

Thus it is evident how very properly the discussion of age should take precedence of other questions forming the subject of a course of Forensic medicine; and it shall be my aim, in the present lecture, to point out to you the mode in which the physical proofs and evidence of age may be ascertained.

Definition.—Age, as the term is commonly used in legal medicine, implies the time of life—the period of human existence which one has attained, or in which an individual lives.

Object.—The determination of age is sometimes attended with difficulty. In certain cases it can be pretty exactly effected, as in the infantile or foetal periods; but, in general, we can do no more than come to certain average results: we cannot pretend, for instance, to fix the age of an individual, except in very peculiar circumstances, to the day, week, or perhaps month, which he has reached; but what we design to do, and, in general, can do, is to determine the period up to which he has lived—each period or portion of life being distinguished from other portions by a particular set of developments which produce marked changes in the person.

An acquaintance with the laws of growth necessary.—For a task of this kind, we must be prepared by being acquainted with the laws of growth. Now, these laws can only be fully appreciated by taking a view of them as they may be observed in operation, from the very earliest point at which they can be traced. In order to have a complete survey of the changes occurring in the course of time in the human being, we must therefore begin with the foetus, and even the embryo, and carry our observation through all the subsequent stages of existence to maturity and decline.

AGE OF THE FŒTUS.

I must premise that it will be necessary to be much more full and minute in treating of the first periods of life than those which will subsequently engage our attention. The reason is this—that so many purely medico-legal questions relating to pregnancy, proclivity, &c., are chiefly dependent on the appearances indicative of age, which are observed in the expelled ovum or foetus. We shall, therefore, com-

mence with intra-uterine life: and in doing so, will freely avail ourselves of the most authentic sources of information which have of late been opened to us.

Earliest appearance of the ovum and embryo.—According to some of our ablest English obstetricians, nothing like an ovum, containing a definable embryo, can be detected in the uterus before the 20th or 22d day after conception. Haller says that the embryo is not perceivable till after the 15th or 20th day. Of this period it is generally admitted that several days are consumed before the ovum reaches the uterus. In rabbits, three days elapse, and in the bitch, from six to eight, while the ovum is being carried along the fallopian tube to be deposited in the uterus. Is it likely that it should be less in the case of the human female, where there are so many disturbing causes, physical and moral, to interfere? And if this be so, what are we to think of the story published by the late Sir Everard Home, in the *Philosophical Transactions* for 1817?

Sir Everard Home's eight-day case.—A female servant, aged 21, left her master's house in the forenoon of the 7th January, 1817, and returned in the evening, complaining of illness. It was her regular time for being unwell, but no catamenial discharge took place. She continued melancholy and ill, and on the 13th had a fit of epilepsy, followed by delirium. She died on the evening of the 15th. On examining the body after death, the uterus, according to Sir Everard, appeared to be impregnated. The organ was removed and put in spirit. In its interior, towards the os tincæ, was observed, after a close search, a small body—a corpuscle—so small, that Mr. Bauer, the microscopist, compared it to the egg of an insect: it required an excellent instrument to find out what it was—and behold it was an embryo! But the whole narrative is questionable. There is no sufficient evidence that the woman was pregnant, and even if she had conceived, it is scarcely probable that the ovum could have reached the womb. Besides, the human ovum is spherical—not like a minute grain of barley, as represented in the plate attached to Sir Everard's paper: nor would it have required the aid of a microscope to examine it even at the earliest. The additional absurdity of supposing it an embryo, destitute of its envelopes, crowns the whole. In short, though this case has been implicitly received by several authors, it has, on the other hand, been generally scouted by competent judges. The state of the female, who was, probably owing to some accidental cause, labouring at the time under suppression of the menses, is sufficient to account for the appearances noticed in the interior of the womb: and

there is every reason to believe with Velpeau, that what Sir Everard Home took to be an embryo, was nothing else than a particle of mucus!

M. Velpeau's case of twelve days.—Velpeau, one of our ablest authorities on the subject of embryology, tells us that he has had on three occasions an opportunity of examining the ovum when it could not have exceeded *twelve days* from conception. Its bulk was then about that of a moderate sized pea. In two of these instances he could not satisfy himself that he really detected an embryo in the interior. But the third case he considers as probably the most remarkable ever met with. Here are figures of the ovum entire, and laid open; they are drawn of the natural size—fig. 2 being a little spread out.

FIG. 1. and FIG. 2.—An Ovum and Embryo of twelve days.

The history of this ovum is curious, and is thus related by M. Velpeau. A midwife who attended his lectures—as many intelligent females in the French metropolis do, in order to prepare themselves for subsequent practice,—happened to be at her menstrual period, and just as it ceased, her husband returned from a journey which had detained him from home for six weeks. No matrimonial intercourse occurred till the following day: and exactly on the thirteenth day after, she aborted of the ovum in question—so that it could not have been more than 12 days old. She sent it immediately to M. Velpeau, who values it, very properly I think, as one of the most precious that has ever fallen into the hands of an embryologist.

In the details which I am now about to give you, it is not my intention to present anything like a complete account of the structure of the embryo: my principal object is to call your attention to the size and proportions of the ovum and its contents, at different periods of intra-uterine life: so that should you be called upon as medical jurists to state your opinion of the age of an expelled ovum or fœtus, you may be able, with some confidence, to do so.

At the twelfth day, then, the ovum, which is about the size of a pea, is perceived to be covered with a villous shaggy outer coat, the chorion: the flocculent part, which becomes more circumscribed subsequently, being that which forms an attachment to the decidua, and constitutes the placenta. The embryo at this period, as represented in the above figure, is semi-

lunar in shape, and rounded pretty equally at both ends. The globular appearance in the second compartment of the opened ovum (and *d* in fig. 3) is remarkable: it is the umbilical vesicle—an organ peculiar to the embryo in the first few months of its development.

Three weeks to a month.—About the 21st day the ovum appears to be as large as a hazel nut. When laid open, as in the annexed figure, (fig. 3,) it looks, of course, much larger.

FIG. 3.—Ovum and Embryo at 21 days—the Embryo seen through the Amnion.

The embryo now measures two or three lines in breadth, and probably its length, were it straightened out, would be from three to five, or about half an inch.

The different parts of the face become distinguishable at different periods. The aperture of the mouth is seen very early—say from the 12th to the 20th day. The nose, or at least the nostrils, at about 30 days: the prominence, not till five or six weeks, perhaps. The eyes are observable by the fourth week, if not earlier. The rudiment of the ear may be perceived as early as the 30th day: but that part undergoes no remarkable development for six or seven weeks. Towards the expiration of the first month, the ovum has attained the size of a large nutmeg.

From four to six weeks.—The ovum about the sixth week is nearly as large as a hen's egg; and the embryo is about an inch in length. The extremities sprout forth from the trunk like vegetations, all about the same time. At from thirty to forty days the fore-arm and the leg may be distinguished, and the points of the fingers and toes are to be perceived. The foot is even now distinct from the hand, evidently displaying what is to be its future function—to form the pedestal of the figure. It is remarkable, that about the expiration of the sixth week a point of ossification may be detected in each half of the lower jaw; as also in each clavicle.

Two months.—The embryo, or, as it now begins to be more properly called, the fœtus, measures above an inch and a half in length; it weighs about half an ounce,

Rudiments of the lungs are visible in the interior, and there are points of ossification in the frontal bone and some of the ribs. The placenta has assumed a distinct form, and the umbilical vessels become tortuous. The sex is scarcely yet distinguishable.

FIG. 4.—Fœtus of about ten weeks, somewhat magnified by the spirit in which it is preserved.

Three months.—The fœtus is now nearly three inches long, and weighs about an ounce and a half. The fingers are very distinct. The eye-lids are formed, and the membrana pupillaris is perceptible. The ventricles of the heart are separated; the sexual parts prominent; the umbilical vesicle has disappeared.

FIG. 5.—Fœtus between three and four months, as seen preserved in spirit.

Four months.—Above six inches long, and three ounces in weight. The nails begin to be observable; there is meconium in the duodenum; some points in the sacrum ossified; the mouth large and open; the skin of a pinkish hue.

Five months.—The fœtus has now attained the length of about seven inches, and it weighs about seven ounces. The head and heart both comparatively very voluminous; the kidneys large; the gall-bladder distinct; rudiments of the teeth may be detected, and there is a point of ossification in the calcis.

Six months.—Above ten inches in length, and the average weight a pound. The membrana pupillaris is still observable; feet of a purplish red colour; a sebaceous secretion begins to be formed on the skin; a few silvery hairs are observed on the head; a serous but not bitter fluid in the gall-bladder; the testes close by the kidneys; meconium in the small intestine; ossification in different parts of the sternum.

Chaussier's rule of admeasurement.—It is worth observing, that about this time the middle point of the whole length is usually found at the lower extremity of the sternum, whence it gradually descends in the succeeding months, till, at the mature period, it reaches the umbilicus. For this character in the foetal growth we are indebted to M. Chaussier, who founds upon it the practical rule,—to take the length of the fœtus, and then observe to what point half that length reaches: if it extend to the lower end of the sternum, it has attained its sixth month; if the navel, the ninth; and so for the intermediate spaces. But it is right to add, that competent authorities have questioned the correctness of this rule: among others Mende, in his *Ausführliches Handbuch* (which, by the way, contains the most elaborate account I have seen of the growth of the fœtus), asserts, that however plausible it may appear, it is not to be always relied on. "The middle point," says he, "by no means corresponds to the same part of the body in fœtuses of the same age: a fact for which we might be prepared by considering that the several sizes of the fœtus depend, now on its large head and neck, now on the trunk, and again on the magnitude of the limbs. This I have verified by numerous measurements, taken with great care and pains; and the conclusion I have arrived at is, that the directions laid down by Chaussier are uncertain for practical purposes, and more particularly for those of the medical jurist."

Seven months.—Length above twelve inches; weight from three to four pounds. The skin firm, of a pink colour, and covered largely with the sebaceous coat. The membrana pupillaris generally disap-

pears in the course of the seventh month; the eye-lids are no longer glued together; the nails do not reach the ends of the fingers. In the astragalus there is observed a point of ossification; the meconium diffused through the whole length of the intestine; the left lobe of the liver almost as large as the right. The lungs of a reddish brown colour, and of a compact liver-like structure, occupying the sides and back part of the chest; the testes have descended a little from the kidneys; the brain comparatively firm, but without any observable deposition of white substance.

Eight months.—The foetus now measures from fourteen to sixteen inches in length, and weighs commonly about four or five pounds. The nails have reached the tips of the fingers; the quantity of sebaceous matter deposited on the skin is considerable; a point of ossification may be noticed in the last vertebra of the sacrum. The brain presents an appearance of convolutions; but still there is no white substance. The testes have reached the inguinal rings.

At nine months, or mature.—The length of the mature foetus averages above eighteen inches, and the ordinary weight is between six and seven pounds. Half the length reaches to the umbilicus, or very nearly. There is more or less hair on the head,—sometimes an inch long. An abundant deposition of sebaceous matter is observed on the skin, and appears to be proportionate to the development of the lymphatic system in the foetus. The lower limbs are longer than the upper; though, measured from the arm-pits to the tips of the fingers, and from the groin to the toes, the reverse would seem to hold. The feet are a sixth of the whole length of the body. The cartilage of the ear is completely formed; there is a point of ossification at the inferior extremity of the femur; the os hyoides not ossified; some appearance of white substance observable in the brain. The liver reaches the umbilicus; the testes have usually passed the rings, and descended into the scrotum; meconium is found in the rectum. The following are the principal measurements of the head, according to Devergie and Velpeau:—

	FRENCH		ENGL.
	In.	Lin.	In.
Occipito-frontal diameter	4	3	4.52
Occipito-mental	5	0	5.32
Fronto-mental	3	6	3.71
Bi-parietal, or transverse	3	4	3.54
Bi-temporal	3	0	3.19
Greater circumference, or			
occipito-mental	14	0	14.91
Transverse	10	6	11.18

Let us now sum up the various points to be attended to in collecting the proofs of foetal age. Nor can we do better than follow the order recommended by M. Devergie. *First*, examine the annexes of the foetus, or, in other words, the ovum itself, independent of the foetus: observe the placenta as to its shape and consistence; the state of the membranes; the umbilical vesicle, if it be present; the funis, as to its length and degree of torsion. *Secondly*, examine the foetus and its organs; weigh it; take its length; observe to what point half the length reaches, and note the insertion of the umbilicus. Let the skin be inspected as to its colour, consistence, and sebaceous coat; observe the nails, the eyes and eye-lids, and the presence or absence of the membrana pupillaris; the nose, mouth, and ears; the abdomen, and the state of the digestive tube; the liver and gall-bladder; the kidneys and renal capsules; the testes or uterus; the heart, with reference to the development of its cavities; the arteries connected with it; the ductus arteriosus; the lungs; the larynx and bronchia. The muscular system; the state of the bones, as to the progress of ossification; and, lastly, the extremities, with a view to the comparative development of their several parts.

Such are the leading characteristics by means of which we are to form an opinion of the age of an embryo or foetus. Where the object is to ascertain the age of a *living* foetus—of course, in *utero matris*, the inquiry becomes equivalent to that for ascertaining the period of pregnancy; but this we reserve for a future lecture. Nor let it be supposed that such researches are merely curious; they are, in reality, important and necessary; for both in a civil and criminal point of view the life of a child, even before birth, is an object of protection with our laws: it is avenged if injury be offered to it; an infant yet unborn is capable of inheriting an estate, and of becoming a legatee, from the moment it is ascertained to be alive.

PERIODS OF HUMAN LIFE.

The periods into which the life of man has been portioned out are in great measure arbitrary. The gradations by which they pass into each other are imperceptible, though the consequent changes are manifest enough. And it has long been popular, as well as convenient, to make a distinction in those periods, or *ages*, as they have been called.

Threefold division.—Some of the oldest authorities, — and Aristotle among the number, — thought fit simply to distinguish the stages of our mortal career into those of growth, perennuity, and

decline, not perceiving, or not caring to notice, that, strictly speaking, no such period as that to which they attached the quality of durability existed,—there being, in fact, no moment during the existence of our corporeal system in which we can be said to be stationary. Letting this pass, however, the threefold division appears to have been early supplanted by another, which seemed more practical.

The Seven ages.—As early as the time of Hippocrates, we find man's life portioned into seven ages. Both Hippocrates and Proclus subdivide the period of growth just mentioned into infancy, boyhood, and puberty—that of perennity into youth and manhood—and that of decline into senescence and decrepitude. Thus we have the authority of distant ages, and of the father of physic, for that division of human life which is popularly recognized amongst us, and which must popularly prevail as long as the writings of our great dramatist are extant—that is to say, as long as our language is understood. You are all no doubt familiar with the beautiful description which Shakspeare has given of the Seven Ages, in the second act of "As you Like It."

It should be mentioned, that attempts have from time to time been made by modern writers to introduce other more brief and comprehensive divisions than those they already found in use: Eschenbach and Haller, and Bernt, for example, adopt a *threefold* partition; Hebenstreit, Ludwig, and Henke, recognize *four* periods; Ploucquet *five*; Orfila also *five*; Teichmeyer, Wildberg, Meckel, and Mende, *six*; Grüner *seven*; and Metzger *eight*. But those who adopt less than six are obliged to subdivide the early periods, thus virtually employing a larger number. I shall only add, that Zacchia, Tortosa, Foderé, and Plenck, are among those who are decidedly for *seven* ages.

Suppose, then, we adopt this popular, and let me also call it physiological arrangement, what are the limits by which each period is to be defined? Here too we shall find a *sevenfold* order the most satisfactory, easy to be remembered, and suited in every respect to medico-legal purposes. The first age commences at birth, and runs on to the 7th year; the second, or boyhood, from that to the 14th; the third, or puberty, from the 14th to the 21st; youth, or juvenility, to about 35; manhood, from that to about 56; senescence, or old age, to 84: after which decrepitude closes the scene. Now it is curious, and worth observing, that all these numbers are multiples of seven. The enumeration may be more striking when arranged thus:—

Infancy.....	0 to 7 =	1×7
Boyhood	7 to 14 =	2×7
Puberty	14 to 21 =	3×7
Youth	21 to 35 =	5×7
Manhood	35 to 56 =	8×7
Senescence	56 to 84 =	12×7
Decrepitude.....	84 to 0	

Climacterical years.—In noticing this coincidence—this curious harmony of numbers—I may take occasion to remark one or two other multiples denoting epochs, to which great importance has been from the earliest times attached. Both 7 and 9 have long been held as mystic numbers: and peculiar influences have been attributed to those years marked by their special multiples. The three most critical epochs in the life of man were supposed to be the seventh return of the seventh anniversary, the ninth of the ninth, but above all, the ninth recurrence of the seventh. The first of these, the 49th year, was called the lesser climacteric—the second, the 81st, the grand climacteric—the third, however, or the 63d year, obtained, *par excellence*, the denomination of the climacteric year. *Ἀνδροκλας*, another epithet bestowed upon the latter, originated in the supposed efficacy of this mystical number in *breaking down* the constitution of man. Sir Thomas Browne, in his *Enquiries into Vulgar and Common Errors*, notices this superstition, and attributes it to the understanding which "ascribeth unto many things far larger horizons than their due circumscriptions require, and receiveth them with amplifications which their reality will not admit;" upon which he proceeds to pour out a profusion of learning in disproof of the common opinion. Richerand also notices the subject in his *Erreurs populaires*. But the impression has been somewhat revived of late, under the patronage of our learned president of the College of Physicians. Sir Henry Hallford, in an ingenious paper, has shown that there exists a disorder to which men are subject about the time of their reaching their 63d year. It is attended, he tells us, with well-marked symptoms, and a peculiar breaking up of the constitution, which is frequently fatal, from not being well understood by practitioners: he calls it the climacteric disease: you will see his account of it in his collection of *Essays and Orations*.

I shall now request your attention to some remarks on the subject of each period of life separately, in the order just now selected.

Infancy.

With regard to the period of infancy, the chief question with which the medical jurist has to deal is—how is he to ascer-

tain the age of an infant within the first months, weeks, nay, days, of its extra-uterine existence? The circumstances under which we may be required to find an answer to this question are of frequent occurrence. I have already alluded to its connexion with cases of infanticide, and shall have again occasion to recur to that fact when treating of child-murder more at large. But suppose, for the present, a child found *alive*, exposed, and suspicion resting on some female who is reported to have given it birth and then abandoned it. If the exact age of the infant can be ascertained, and there be no corresponding signs of recent delivery about the woman, the fact is strongly in favour of her innocence, in spite of all moral or circumstantial evidence to the contrary: if, on the other hand, the signs correspond, there will be a presumption of guilt.

It will be convenient to subdivide the period of infancy into two well-marked stages—first, that from birth to the first eruption of the teeth; and second, the period of dentition, during which the temporary teeth are produced, and comprehending the interval which occurs before the permanent teeth are completed.

(a). *First infancy*.—What are the signs of a new-born infant's age? Our first proceeding with a view to satisfy this inquiry should be to *examine the umbilicus*: to see whether the cord or any remnant of it be present, and what may be its condition.

The umbilical cord, it is known, does not come away, in the generality of instances, till the fourth or fifth day after birth. An obvious inference, therefore, from its *presence*, would be, that the infant cannot have lived five days. We then proceed to examine the *state* of the cord, in order that we may be able to approximate still further to the date of birth: now this we are enabled to do by attending to the valuable observations and rules laid down by M. Billard, and which are thus practically summed up by Orfila and Devergie:—In the infant just born the cord is fresh and firm, bluish, and rounded off; there is blood also in its vessels. The first perceptible change that occurs after it has been divided and tied, is its *shrinking* (*retraction*): this proceeds from its extremity, where the ligature is, to its base at the umbilicus, and is observable in general before the lapse of a few hours. When this process is complete, which it generally is by the close of the second day, the cord is quite soft and flaccid, and a well-marked congestion is perceived around the umbilical ring. The next phenomenon to be noticed is the *drying up of the cord*. It becomes brown

and semitransparent, losing the gelatine which it contains. As its membranes collapse it becomes flattened, and its integument assumes the colour of parchment. This withering (*desiccation*) commences on the first or second day, and is generally completed by the third. It has been attempted to establish a distinction as to this process, according as it may have occurred during life or after death; there being, according to some observers, appearances of inflammation about the umbilical ring in the former case, and not in the latter; but such appearances are not sufficiently constant to warrant any positive conclusion from the fact of their presence or absence. The next phenomenon to be noticed is the *fall of the cord*, which takes place on the fourth or fifth day. Its base dwindles by degrees; the umbilical arteries give way; but the vein lasts somewhat longer. When this occurrence is attended with inflammatory action about the umbilicus, the traces of such inflammation continue till the tenth or twelfth day after birth, the epoch at which cicatrization is effected. As to this latter phenomenon (*cicatrization*), though it commonly occurs at the epoch just mentioned, yet, when the cord is thin, it sometimes takes place earlier—that is to say, in less than ten days. A temporary umbilical cicatrix is first formed, which, in the course of about forty days, gives place to the permanent one.

The next sign indicative of the new-born infant, is the *desquamation of the cuticle*; an appearance which is very different from the peeling off of the epidermis from putrefaction. The desquamation alluded to has not been observed to take place sooner than twenty-four hours after birth; and it is at its height by the third or fourth day. The process usually commences on the abdomen, and then extends successively to the chest, arm pits, and groins, the back, the extremities, the feet, and the hands. In some children the epidermis comes off in the shape of powder—not in scales. If, then, on examining an infant, the *desquamation* be observed, it may be presumed to have been born a day at least.

When we have an opportunity of inspecting the body after death, there are other proofs of early age to be gathered. The *ductus arteriosus* will be perceived, at least contracted, in a child that has survived birth, even though it were but for a very short time. The *foramen ovale*, also, will probably be found to have undergone a change in size and figure; and the *ductus venosus* will perhaps be observed to have sustained an alteration in form. But all these appearances we shall have a better opportunity of noticing when we come

to treat the subject of infanticide, some of the proofs of which depend on the occurrence of those changes in the circulatory apparatus.

Among the signs of age of the new born, we ought not to omit those derivable from the state of the alimentary canal: but they will require only a brief notice. If the stomach be empty, or contain only a little mucus, while the large intestine is still charged with meconium, and the bladder filled with urine, death has probably occurred immediately after birth, —if it be not, indeed, a question whether the infant were not still-born. If, on the other hand, the stomach contain milk, or other alimentary matter, and both bladder and intestine be empty, the child undoubtedly lived for a time. The meconium, it must be recollected, is lodged in the large intestine for some time previous to birth. It is expelled presently after birth. Now the tube has been protected during the detention of the meconium, by a layer of mucus of considerable thickness and consistency. The layer is not removed immediately on the expulsion of the meconium; in some cases it is no longer observable after the first day; but in general we need not expect to find it wholly gone till four days after birth: and when we see it, we may observe that it has contracted a greenish hue. From these facts, M. Billard derives a practical rule:—"If the colon be found of a deep and uniform greenish hue, the meconium has been only recently expelled; the infant must be then one day, and may be at most three days, old. But should the colon have an irregular spotted appearance, the meconium has been still less recently expelled, and the infant is probably three or four days old." It is right to add, however, that these indications are by no means as valuable as those to be procured from the state of the funis.

There are other well-known signs of early infancy, which need not detain us in pointing them out. I allude to the extreme softness of the bones of the head, the open state of the fontanelles, the downy face of the infant, its feebleness, and inferior size. At a period a little more advanced, we may avail ourselves of several moral circumstances in forming our estimate of the age; such as the smiles of the infant, the early dawnings of the development of the mind, and the distinctness with which certain desires and wants are expressed. But we must be cautious, as medical jurists, how we derive more than collateral evidence from such phenomena.

(b.) *Period of first dentition.*—At length the teething period arrives about the sixth or seventh month, and is generally ushered in with a copious flowing of saliva from the mouth. The infant, too, mani-

festes a certain restlessness, and is ever anxious to rub the gums.

The order in which the teeth are cut is worth attending to, although the exact date of the successive appearance of each tooth cannot be precisely stated. First the middle incisors of the lower jaw are observed; then those of the upper to correspond; then the remaining incisors in like manner — first below, then above. Next appear the first molars of the lower jaw, then the opposite ones of the upper. The canine teeth follow; after which the second molars, until the whole *twenty* milk-teeth, constituting the temporary set, have been produced. The process is generally completed towards the end of the second year*.

The following may be considered as an approximation to the average epochs of the appearance of the milk-teeth:—

The two middle incisors, from	5 to 7 months.
The two lateral incisors,	6 to 9 —
Two first molars	8 to 15 —
Two canine teeth	15 to 18 —
Two second molars	18 to 24 —

But there is usually a great diversity in different children, with respect to the time of cutting their teeth. Some are born with their incisors above the gums; others have no teeth at all till the end of the second year; and persons have been known who lived many years without having ever had a tooth.

Growth of the bones.—I have already noticed some of the earliest epochs at which the osseous system begins to be developed, and shall now put together what further points remain to be considered in connexion with infancy. I am anxious to bespeak your attention to this subject, though it may seem somewhat burthensome to the memory, because it is from the progress of the bony structures (thanks to the researches of Beclard) that we may derive some of our best and surest indications of age at every period, but particularly in those of early life.

About the 5th month of infancy, a trace of osseous deposit may be observed in the cuboid bone of the tarsus. The branches of the os hyoides are now ossified, and somewhat later the lower apophysis assumes the same state. At six months, an osseous point is found in the anterior arch of the atlas, and the great wings of the sphenoid become united with the body of that bone. At twelve months, or thereabouts, the middle of the coracoid process of the scapula is generally found to be ossified: osseous points are also found in the heads

* See MEDICAL GAZETTE, vol. xiii. pp. 160 and 287.

of the long bones, the tibia and femur in particular; and the vertebræ have some considerable changes operated on them. There is a point, for example, in the first coccygean vertebra; and the two osseous points in the posterior arch of each vertebra become united. The pieces of the temporal bone are firmly joined.

At the age of *two years*, the epiphyses of the metacarpal and metatarsal bones are ossified: and an osseous germ is found at the lower extremity of the radius. At $2\frac{1}{2}$ years, the patella becomes ossified, and so does the lesser tuberosity of the head of the humerus.

At *three years*, the first molars of the second dentition make their appearance, and about six months later the second molars of the same set.

At *four*, the great trochanter and pyramidal bone of the carpus, also the second and third cuneiform bones, become ossified. Between four and five years, the upper extremity of the fibula, the epiphyses of the phalanges, the trapezoid, and the semilunar bodies, exhibit a bony structure.

At *six years*, the pisiform bone is formed, and the constituent pieces of the ossa ilia are separated merely by a very thin cartilaginous layer: the descending branch of the os pubis, and the ascending one of the ischium meet. Numerous changes also in the progress of the bony formation now occur in the vertebral column: but I find my limits will not allow of their enumeration.

We shall complete our view of the remaining ages in next lecture.

MEDICAL PROBLEMS.

By WILLIAM GRIFFIN, M.D. Limerick*.

HOW ARE NEURALGIC AFFECTIONS TO BE DISTINGUISHED FROM INFLAMMATORY?

IN treating of peritoneal and enteric inflammations, Dr. Abercrombie states, as conclusions from facts, "that extensive and highly dangerous inflammation may exist in the intestinal canal, without obstruction of the bowels, and it may go on to a fatal termination, while these are in a natural state, or easily regulated by mild medicines, through the whole course of the disease."

"That extensive and fatal inflammation may be going on with every variety in the pulse; it may be frequent and small, it may be frequent and full, or

it may be little above the natural standard through the whole course of the disease."

"That extensive inflammation may go on without vomiting and without constant pain; the pain often occurring in paroxysms, and leaving long intervals of comparative ease."

"Keeping in view these sources of uncertainty (he says), our chief reliance for the diagnosis of this important class of diseases, must be on the tenderness of the abdomen. This symptom should always be watched with the most anxious care, *whatever may be the state of the bowels or of the pulse, or the actual complaint of pain*, and though the tenderness itself should be limited to a defined space of no great extent."

Whatever the experience of the profession may have determined with respect to the greater part of these conclusions before the appearance of Dr. Abercrombie's work, I believe it has been always in accordance with the opinions of that distinguished physician on the importance which should be attached to the presence or absence of abdominal tenderness in cases of suspected inflammation; but Dr. Abercrombie was very well aware, when he gave such just weight to this symptom as a means of diagnosis, that in itself it was far from conclusive, and derived its value chiefly from the existence of many other corroborating signs. He states, indeed, distinctly, in another part of his work, "that pain increased upon pressure does not appear to be a certain mark of inflammation in the bowels, for it occurred in Case XXIV. (related by him), in which there was no inflammation; and in several other cases it was met with before, probably, inflammation had commenced. From various observations, he states, he is satisfied that intestine which has become rapidly distended is painful upon pressure; it is, however, a kind of pain which, *by attention, can generally* be distinguished from the acute tenderness of peritonitis."

This point of diagnosis applies altogether to the discrimination of cases of ileus from those of inflammation, and even as such, is, it would appear, often of doubtful value; but in what light must we view it, in reference to those frequent neuralgic affections, which, whether hysterical or the results of irritation of the spinal cord, are often established suddenly, with little preparatory disorder, and with no distension of the

* This article, which has appeared in the *Dublin Journal of Medical Science*, we republish at the request of the author, who has corrected several errors which had crept into the original impression.—ED. GAZ.

intestinal canal to account for the acute tenderness on pressure? No medical man is now ignorant of the fact, that the contents both of the thorax and abdomen, as well as their parietes, are subject to attacks of a violent pain of a nervous or spasmodic character, yet with acute soreness to the touch, as in pure inflammations. These are so widely separated from the latter in their nature, and require such a very different, I might almost say opposite, mode of treatment, that a correct diagnosis becomes a matter of still greater interest than in cases of ileus. There are few instances of ileus in which one effective bleeding might not be of effective service, while there are few of hysterical pseudo-peritonitis, or enteritis, or of similar affections arising from irritation of the cord, which might not be made worse, or indefinitely protracted by it; yet we find in our best elementary works on this subject a most perplexing indefiniteness, a diffuseness of description, and a labouring at discrimination, wholly unworthy of the present improved state of medical science, and unnecessary, if any real or essential difference of character could be pointed out. It is, indeed, because there is an essential agreement in all material points, that our attention is directed to the attitude, the expression of countenance, the manner of complaining, and even the temper of patients, although there must be sometimes very considerable differences as to all these in individuals similarly affected, and in any case no slight degree of experience is required to form a proper estimate of their value. We are told that one affection is frequent, the other rare in comparison—that females are more liable to it than the other sex, and those of sedentary habits in towns, than those leading active lives in the country; all of which might be very useful information, so far as it tended to corroborate features of a more marked expression, but is essentially loose and vague if considered by itself. Again, we are reminded of one or two truisms; that if a disease has lasted long and done no mischief, or if it has been aggravated by an antiphlogistic treatment, its character is not inflammatory. We may thus arrive at a correct diagnosis about the time the complaint ought to be cured and forgotten. But the climax of our difficulties on this subject is displayed in the admissions of experienced phy-

sicians, that their practice, when in doubt, is to run the risk of erring on the safe side, and treat the disease as inflammatory;—perhaps a judicious plan enough under the circumstances, but certainly not so consolatory to the patient, nor, as I have elsewhere remarked*, very creditable to medical science. It may be questioned, too, whether a rule of the kind with young physicians would lead only to errors on the safe side. I have seen one valuable life lost, and others endangered, by such practice, and sometimes the antiphlogistic treatment vigorously adopted; not, indeed, where doubts existed in the mind of the practitioner, but where the cases were altogether mistaken.

I am far from assuming to myself a perfect freedom from perplexity in all possible cases simulating inflammations of internal organs which may come before me, but with the facts I have stated impressed on my mind, I cannot but feel that the experienced physician is usually too well satisfied with that indefinable power of recognizing or identifying diseases almost unconsciously acquired in the course of long practice. In reflecting on the melancholy steps by which it is attained—on the sad, though perhaps excusable, errors committed—he consoles himself with the conviction that such experience only could gift him with a knowledge which neither books nor lectures had taught him, when he should rather feel that the true reparation to his conscience, the real duty he had to perform in acquittance, was to prevent the occurrence of such mistakes with others, by analyzing the characters of those perplexing diseases, and endeavouring to trace the sources from which his late discrimination was derived. It is not enough for a practitioner in a difficult case to be assured he is himself capable of determining its nature; he should consider whether his knowledge or ability admits of being communicated to others; and when he believes it is, but not until then, he may also believe that he has acquired information of infinitely greater value to the public than any thing it could have suffered from his early mistakes.

I have been led to indulge in these observations in consequence of the apparent inattention with which a sug-

* See Treatise on Functional Affections of the Spinal Cord.

gestion with respect to the diagnosis of neuralgic affections, proposed by me some years since, was received by the profession: I then stated, that in any doubtful cases I believed if tenderness on pressure *at the portion of the spinal column corresponding with the disturbed organ* existed, it might be considered decidedly neuralgic; but if no such symptom was found, it was probably inflammatory. The suggestion was then offered rather as a result of individual observation, which I was anxious should be tested by the universal experience of the profession, than with a view of claiming attention for an incontrovertible fact; but I have since so repeatedly derived ready assistance in simulated inflammation, by assuming it as such, and have had the diagnosis so invariably borne out by the result, that I do not now hesitate to assert, it is almost the only single symptom upon which a young practitioner can rely without danger.

Without entering into the question of the nature of spinal irritation, which I have discussed at large in another place, I may be permitted to claim the reader's attention to two points connected with it, which must be regarded as physiological facts. That the spinal cord, as the experiments of Le Gallois have shown, is composed of portions independent of one another in their powers and functions, being centres from which the nervous actions of corresponding parts of the body emanate, and to which they tend; and, secondly, in conformance with the well-known law, by which the pain and tenderness arising from disorder at the origin or trunk of a nerve, is referred to, or felt at its extremity, that affections of the spinal cord are not usually recognizable by pain at the part diseased, but at the terminations of the nerves in distant organs arising from it. From these facts there is one undeniable inference in determining the diagnosis of cases resembling inflammation,—that wherever spinal tenderness exists, we must at all events set down pain and tenderness (the two most important symptoms in assisting us to detect internal inflammation) as wholly valueless; inasmuch as, whether there be inflammation or not, these are not peculiarly the results of it, but may arise also from the tender state of the cord. I might perhaps go much farther, and assume, that where spinal

tenderness exists, there also exists a state of the system scarcely compatible with acute inflammation.

If, then, pain and soreness on pressure, those supposed characteristics of inflammation, are of all others the most equivocal symptoms, belong as certainly to irritative as to inflammatory affections, and almost necessarily exist if there be acute spinal tenderness; what is to be our guide in deciding the diagnosis when called to a person suffering with violent pain of side, feverishness, difficulty of respiration, and soreness of the intercostal muscles; or with violent pain in the abdomen, accompanied by exquisite tenderness to the touch, and perhaps constipation and vomiting—if *we do not examine the spinal column?* We want to ascertain the simple fact in the first instance, of whether the pain is in the viscus supposed to be affected at all, or whether it be merely in the thoracic or abdominal parietes. And since the patient shrinks and complains on pressure in both cases, what, I ask again, is to be our guide, *if we do not examine the spinal column?* Are we to depend upon speculations on the attitude, expression of countenance, temper or manner of a patient, when we can at once lay a finger on the spine, and detect both the cause and nature of his complaint.

If in the former case we find acute tenderness of some of the dorsal vertebrae, or in the latter of some of the lumbar, I do not hesitate to say, the one is not pleuritis, nor the other enteritis, nor will either bear large depletion with impunity. The pain and tenderness are merely referred to the extremities of the spinal nerves, ramified through the intercostals or abdominal muscles, from the affection of the corresponding portion of the spinal column, and indicate nothing whatsoever of the state of the viscera internal to them, which usually excites so much alarm. If these are facts, and I believe few will deny them to be so, on examining for themselves, is it not absolutely leading the young practitioner into those mistakes which we so much deprecate, to associate pain and tenderness on pressure so exclusively in his imagination with inflammatory diseases? Is it not strange too, that cases are every day published in our periodicals, with dissertations on the difficulty of their diagnosis, without the slightest allusion to the spinal cord, the

state of which, in every case of presumed inflammation, our present knowledge of physiology must show us the necessity of ascertaining*. One would suppose where the obscurity of the diagnosis is often so undeniable, that any adventitious light which could be brought to bear upon it would be sought for with avidity, but this, every day's experience assures us, is very far from the reality. As illustration is very generally more impressive than argument, I shall offer two or three cases to the consideration of the reader.

A young woman, aged 25 years, was attacked with pain in the bowels at night after a feeling of chilliness. She took some essence of peppermint and went to bed, but the pain gradually increased, and at two o'clock in the morning she took twenty drops of laudanum. At seven o'clock, the pain still continuing, she took castor oil, with ten or fifteen drops more of the laudanum, by the directions of an apothecary, and soon after ten drops were repeated in a saline draught. I saw her at one o'clock, and found her writhing with pain, chiefly round the umbilicus and to the right side. It became more violent by fits like colic, though never entirely subsiding, and during the intervals of comparative relief, she sometimes threw her arms about restlessly, sometimes lay as if insensible, with the eyes turned

up and the lids half open. Her complaints were low, scarcely audible, her respiration painful when deep; turning from side to side increased her pain, although when the paroxysm occurred she turned sometimes on her face. There was excessive tenderness of the abdomen, the least pressure making her scream. She had been constantly vomiting for the last few hours. The castor oil had operated once scantily; her pulse was but little quickened, and there was no heat of skin.

Here was a case of constant pain in the abdomen, chiefly about the umbilical region, liable to severe exacerbations, attended by exquisite tenderness on pressure, vomiting and constipation, and continuing for twenty-four hours. I am convinced that almost any young physician would have felt great difficulty, indeed almost an impossibility, of determining, from a consideration of the symptoms, that the complaint *was not inflammatory*, and I believe that the great majority of either young or experienced ones would at once infer the existence of inflammation, and bleed. I say so from having witnessed it, and from having early in my own professional life always prescribed in such cases with timidity, as if I felt that all consideration of the symptoms led to little better than conjecture. I had now, however, new ground for a diagnosis in the state of the spinal column, on examining which my mind was set at rest. As soon as I pressed on the upper lumbar vertebræ the girl started violently, caught my hand, and complained that I had hurt her dreadfully: the pressure, she said, had increased the abdominal pain: she had never had any hysterical attack in her life. I ordered the abdomen to be fomented freely, and gave her five grains of calomel with half a grain of opium, directing five grains of aloes and five of extract of henbane, to be taken every two hours. The calomel and the first dose of the aloetic pills remained on the stomach, but the succeeding doses were rejected; a purgative draught was also thrown off: she then got a purgative enema, which was repeated in an hour, but both passed off without any appearance of *feces*. The vomiting, pain, and tenderness of abdomen, continued very severely throughout the evening. At night she got a turpentine enema, and was placed in a hot bath,

* There was a paper from Dr. Samuel Cusack in one of last year's Dublin Medical Journals, "On certain Nervous Affections occurring principally in Females." It was an essay, in fact, on the treatment and diagnosis of those chronic pains below the mammæ, or between the false ribs and ileum, so often mistaken for phthisis, pleurisy, liver complaint, &c., to which public attention has been directed of late years by several writers, as instances of spinal irritation. Dr. Marshall Hall described them long since in his work on Diagnosis, and more at large in his work on the Diseases of Females. Mr. R. P. Player published a letter on the subject as long ago as 1821. Dr. Brown, of Glasgow, published precisely similar cases in 1828, demonstrating the connexion of the pain with the spinal cord, and since then we have had essays from Dr. Darwall, of Birmingham; Mr. Teale, of Leeds; and Dr. Marshall, of Manchester; all pointing out the nature of those pains, and the little connexion they had with a disease of the viscera apparently affected. It is of course open to any physician to publish cases and observations in support of particular views, however frequently placed before the public already by others; but it seems singular Dr. Cusack should conceive it necessary in 1834 to publish an essay on these affections, not only without the slightest allusion to their possible connexion with the state of the spinal cord, but without the least mention of any of those writers, to whom we are indebted for both the descriptions which he gives, and a diagnosis so much more accurate than his, in its not omitting an examination of the vertebræ.

which gave some relief, and procured a scanty evacuation. The pain, however, soon recurred, and she was ordered a grain of opium, to be repeated every hour until it should subside. The bowels were freely moved soon after taking the first dose, but she did not experience any considerable relief until she had taken the third, after which she fell into a sound sleep, and in the morning was in every respect improved. The pain had altogether subsided, and the exquisite tenderness was now felt in the right epigastric region only. She had threatenings of a return of the attack in the course of the day, but it was readily subdued by a repetition of the opiate. On the following morning there was scarcely any pain or tenderness, and if the complaint had been inflammatory, I would now have left the patient's bowels perfectly at rest. But believing it to be an affection of the spinal cord, arising from disorder of the digestive functions, I ordered another dose of castor oil, which operated freely, and was followed by no recurrence of the attack.

Mrs. —, aged 30 years, of a full habit, complained of pain in the right iliac region, which gradually increased until the whole of the abdomen became sore to the touch; on the third day she took castor oil, which operated freely, but gave no relief. I saw her on the fifth day, when she complained of being much worse, and directed her to get to bed, to have the bowels fomented, and to take pills of aloes and henbane every second hour until relief was obtained. In the morning I received a letter, stating that she had been in agony all night, was much swelled, had not had her bowels moved for three days, and was now feverish and throwing every thing off her stomach. I became excessively alarmed, and regretted I had not bled her on the night before. On arriving at her residence, I found her complaining of violent pain all over the abdomen, but most acutely in the right iliac region, and almost down to the pubes on that side. There was fulness of the bowels, and the greatest tenderness on pressure. She could not bear the slightest touch in the iliac region, and one spot she described as exquisitely sore. It was on this account, perhaps, that she bore the weight of my hand laid flat, and pressed very gradually, better than pressure with the points of the fingers, as, in the former case, the pressure on the *most painful spot*

was not so direct. Her pulse was ninety-six, her skin feverish, and tongue white; she had nausea and occasional vomiting, and could not turn or move in the bed, without considerably increasing her sufferings. The only symptom that could lead me for a moment to doubt that I had here a case of very serious inflammation to deal with, was the expression of the countenance, which did not betray the deep anxiety and distress I have usually seen in the inflammation of vital organs, although her own description of her suffering was sufficiently alarming.

The treatment of the case with decision and confidence now depended altogether on the examination of the spine. If I found a state of increased sensibility and excitement of that part of the cord which gave origin to the lumbar nerves, the pain and tenderness of abdomen would be accounted for, and I need not infer a more alarming cause for them. If, on the other hand, there was no spinal tenderness, the existence of acute inflammation was almost certain, and the most active treatment was demanded. On pressing the spinal column, as soon as I reached the lumbar vertebrae she started and screamed aloud. She also felt excessive pain on my touching the sacrum, or making pressure behind the trochanter, or at the front of the hip-joint in the groin. I therefore unhesitatingly concluded it was one of those nervous affections simulating inflammation, in which the progress of the case fully bore me out. A few leeches were applied to the most painful part of the abdomen, and a grain of opium was directed every second or third hour until there was some abatement of pain. She was also directed, as soon as the vomiting abated, to resume the pills of aloes and henbane, and take a dose of castor-oil. She got considerable relief, but passed a restless night. In the morning she took the aperient medicine, which operated freely, and now had pain occasionally only, and at long intervals; the vomiting had ceased, but the soreness of the abdomen was still exquisite in the right ileum and groin, and she screamed when I pressed on the vertebra, or immediately behind the trochanter. Fomentations were now directed; belladonna plasters were afterwards laid over the painful parts, and the opium pills were given every fifth or sixth hour. She spent the day well, but the pain recurred in the night very

severely, and was relieved by the anodynes. Next morning the bowels were again moved, but the soreness on pressure, or on moving much in the bed, still continued. The case went on in this way for several days, abating very gradually, but the soreness of the abdomen and of the hip-joint was not perfectly removed until she was for some days driving out in her carriage.

I attended this lady afterwards for an attack of acute bronchitis, which was of a similar character in its advanced stages. The cough, oppression, and expectoration, were evidently the result of nervous irritation, and required tonics rather than the continuance of any antiphlogistic treatment. She told me that in a former illness, which she called inflammation of the lungs, the doctor had bled and, I believe, blistered her more than once; that she was going on from bad to worse, with incessant cough and debility, until at last, in defiance of all advice, she took a glass of pure wine, which cured her like a charm. I mention this, not that one can infer much from such loose statements, but because it gives some idea of the irritability of her nervous system.

Mrs. —, of a delicate nervous habit, after a natural labour, had internal hæmorrhage, with pallid countenance, cold clammy sweats, chilliness, and an almost imperceptible pulse at 156. The hæmorrhage ceased on the extraction of several clots with the hand, but the debility continued to an alarming degree for several hours. She had large doses of laudanum, with dilute sulphuric acid, through the night, which seemed to relieve her much; but in the morning the debility was still great, the pulse weak at 130, the features sunk, and the respiration much hurried. On the following evening she had a severe rigor, and was soon after attacked with pain and tenderness in the uterine region, excessive pain in the head, brow, and eyes, with sickness of stomach and vomiting. There were thirst and heat of skin, and the pulse became rather hard at 140; the tenderness on pressing over the uterus was considerable, the pain constant, the lochia diminished. On examining the spine, there was found acute tenderness of the lumbar vertebræ, upon which it was assumed to be a case of nervous irritation, and not inflammation. A dose of calomel with extract of henbane was given, fomenta-

tions were applied to the lower part of the abdomen, and she got diaphoretics at intervals. Under this simple treatment the symptoms declined, and on the succeeding night she felt quite relieved; the lochia and secretion of milk becoming abundant, and the pulse soft at 126. After the lapse of some days she was up and well.

Mrs. M——, a married woman, aged 26 years, had very severe flooding in her lying-in. On the fifth day after, she was seized with pains in the abdomen, attended by excessive soreness to the touch, and fever. She got castor oil on the sixth day, which operated twice without giving much relief. In the evening she had a slight rigor, and felt very weak. The milk had left her from the first moment of the attack, and the lochia had nearly ceased. I saw her for the first time on the night of the seventh day from her delivery, and found her lying on her back, with her knees up, complaining much, and incapable of the least motion on turning to one side or the other without the greatest torture. The pain was constant, but was increased to an excessive degree at intervals; coughing was very distressing to her, and the least pressure on any part of the abdomen made her scream. Slow, steady, cautious pressure with the flat of the hand was unbearable, but she could stretch down her limbs without increasing her sufferings. Her countenance, which was pale from the flooding, had an expression of distress, and the brows were knit as with pain. The skin was warm, the tongue moist and white, and the pulse weak, at 112. There was excessive tenderness of all the lumbar vertebræ. The abdomen was fomented, and she got two grains of calomel and a grain of opium every third hour. After the second dose the pain abated, and she got a good deal of sleep; but in the morning the symptoms returned, and the pills were resumed with the same good effect as before. The tenderness of abdomen was now rather less, though the bowels appeared more full, not having been moved for the last forty-eight hours; she could turn from side to side with less suffering; the pulse still 112, and the skin warm and moist; she took castor oil, and afterwards pills of aloes and extract of henbane every second hour, which operated freely; she passed a tolerable night and seemed easier, but got the pain more violently than ever on

the following morning, when it was relieved by forty drops of laudanum; it continued in the intervals of these paroxysms, but not severely. In the evening the paroxysm recurred, and was again relieved by the laudanum. Notwithstanding these recurrences she felt herself on the whole much better, could turn from side to side with more freedom, and wished for nourishment; she complained of some headache. She was now directed to take three grains of sulphate of quinine three times a day, and to repeat the laudanum if seized with the pain. I also allowed her to get a little chicken broth or beef tea. She passed a good night, and although the pain recurred at intervals on the following morning, it was much less severe; she threw up some aloetic and benbane pills which she had taken to free the bowels; the abdomen, though still painful on pressure, was much less tender; the soreness of the spine was nearly gone, and her milk was returning. As her bowels had not been moved for the last thirty-six hours, she got some castor oil, and the quinine and broth were continued; she complained much of headache.

The pain recurred again violently in the night, soon after which the flooding returned for a short time, and then ceased. The pain was relieved by a grain of opium; felt much better through the day, and ate a little meat without permission; the soreness of the abdomen almost gone, and none whatsoever of the spine; her headache was better; she continued her quinine and nourishment, and was well in a few days*.

* The above case, at the first moment I was called to it, so perfectly answered the descriptions given of simple peritonitis (see Abercrombie on the Viscera, p. 151), and so truly resembled the cases of that disease which had fallen within my own experience, that I watched its progress with much anxiety. I was, indeed, somewhat distrustful of the diagnosis; for although the extreme tenderness of spine would fully account for the tenderness of abdomen, the great torture experienced on the least motion from side to side was a symptom more characteristic of true peritonitis than of a neuralgic affection; the progress of the complaint, however, fully satisfied me of its nature. I believe there is no practical physician will assert that a case of acute peritonitis would have been arrested by the treatment adopted, which was, in fact, little else than palliative. It was only on the first day of my attendance that the opium, combined with calomel, was given with any regularity, five grains having been taken within twenty-four hours; for although the pain recurred with equal violence, subsequently she had seldom occasion to take an

I might multiply cases of this nature to an extent that would be tiresome, without making the point much clearer. Perhaps it may be said, that an experienced eye would have detected some anomalous symptoms in all of these, which would have led to doubts of their inflammatory nature. I am not disposed to deny that much may be inferred in such attacks from the suddenness with which violent symptoms supervene, the absence of deep distress and anxiety of countenance, and, above all, from a freedom in the movements of the lower extremities unusual in acute abdominal inflammations. There was, indeed, at least one of these discrepancies observable in a greater or lesser degree in each of the cases detailed; but how are young practitioners to form a diagnosis on such grounds? People suffer similar degrees and kinds of pain with very dissimilar degrees of fortitude; and, at all events, any reasoning on such signs must be founded on comparisons, which, to be worth any thing, would imply an experience no young practitioner can be supposed to possess.

In all acute inflammations of vital organs, I believe that no spinal tenderness will be found, except where it existed previous to the supervention of the attack*, or where the spinal cord itself happens to be the seat of such inflammation. In all neuralgic affections, on the contrary, tenderness of some portion of the spinal column, *usually that corresponding to the affected organ*, may be detected, except in some rare cases, in which it seems probable the ganglionic nerves alone are concerned. As these cases must still present a difficulty in their diagnosis, we must rest contented with those general characteristics, which, however vague or liable to lead us into error, are all we have to guide us, and all we have hitherto had to determine our opinion in that large class of neuralgic affections, for the detection of which I have here been offering a new, and I believe less doubtful sign.

opiate more than once or twice in the day. I may, however, point out one symptom in which the case differed from peritonitis—the ease and freedom with which she could stretch down her limbs. In spinal affections the least motion of the spine, especially turning or twisting motion, will sometimes increase the abdominal pain, but it scarcely ever occasions difficulty or uneasiness in the motions of the lower limbs.

* Some writers on spinal irritation state that they have found spinal tenderness, with inflammation of liver.

The observations offered respecting the diagnosis of cases resembling acute inflammations, apply with almost equal truth to those resembling chronic diseases; I mean those pains affecting the chest, and attended by cough and perhaps oppression, leading to apprehensions of phthisis—the side, between the false ribs and ilium, suggesting affections of the liver or bowels—or the pubic region simulating disease of the womb or ovaries. It is, however, wholly unnecessary to extend this paper to an unreasonable length on the subject of those nervous affections, the nature and diagnosis of which I have discussed so fully in another place; I need only remark, that deducing inferences from acute or chronic pain, apparently affecting any viscus, without examining the state of the spinal cord, seems to me little less absurd than omitting to examine the state of the hip-joint in those painful affections of the knee, the nature of which is not immediately obvious. In either case the disease may not exist at all in the part apparently affected; and the real source of the pain can only be ascertained with certainty by an examination of the origin of the nerves distributed to it, or of any organ with which the part affected may be supposed to sympathize.

ON THE

THERAPEUTICAL EFFECTS OF IODINE,

GIVEN IN VERY LARGE DOSES,

In the forms of Iodide of Starch, Hydriodic Acid, and Iodide of Potassium.

BY ANDREW BUCHANAN, M.D.

Junior Surgeon to the Glasgow Royal Infirmary.

[Concluded from p. 47.]

Noli me tangere.

UNDER the head of *noli me tangere* and *lupus*, surgeons comprehend certain ulcerative affections of the nose, the intractable nature of which seems to have suggested the first name, while the second is expressive of the wide-spreading destruction of parts which they not unfrequently occasion. There appear to be three distinct affections to which these names are often indiscriminately applied. The first seems to have its seat in the bones and cartilages of the

nose. The ulcers of the surface occur only on the nose, or on parts in the immediate vicinity, being apparently a mere secondary affection, excited and kept up by the deep-seated irritation. The other two diseases have their seat in the cutaneous tissue; the evidence of which is, that they often affect other parts of the skin, as well as that covering the nose. The one appears to be a disease of the strumous kind; it comes out in the form of papulæ and small pustules, having irritable inflamed bases, which speedily become the seat of ragged superficial ulcers. The other is the cancer of the skin, which, while it may occur in other situations, is very often observed on the nose.

The two following cases are examples of the first and second of these diseases. In the first a complete cure was effected under the use of iodine. It ought, however, to be borne in mind, that in such cases, on the diseased bones, which are the great source of irritation, being discharged, a spontaneous cure is often effected. In the strumous disease of the skin the benefit obtained was much less considerable.

Agnes M'Ilwee, æt. 12, spinner. January 7th: Left half of upper lip is the seat of an irregular unhealthy ulceration, with thin edges, no granulations, and pretty deeply excavated in several places. Discharge is thin and serous, concreting into yellowish scabs. Integuments stretching from nose upwards and outwards towards right malar bone, are red and chapped. Disease appeared about twelve months ago, healed spontaneously, and reappeared six weeks since, cold weather seeming to be its exciting cause.

Three years ago ulceration of throat attacked her, and ended in complete destruction of velum palati, and partial destruction of roof of mouth. Several pieces of bone were discharged, and there is now an oval opening into nostrils, the posterior part of septum of which is destroyed. No pain in diseased parts; glands under angle of jaw considerably enlarged. General health pretty good. No treatment.

8th.—Sum. ter indies Iodid. Amyl. 3j. m. s.

13th.—Little change on symptoms.

Auguat. dos. Iod. Amyl. ad. 3ss. ter indies.

27th.—Ulcers of lip every where

cicatrized, except a stripe along margin of mouth, which is covered with a dry scab. A considerable portion of septum and maxillary bone have been removed, and there is no longer any discharge from nose. Medicine agrees well.

Feb. 23d.—Dismissed cured.

Ann Smith, æt. 17, weaver: March 6th.—About six years ago, observed a small excoriation, discharging a thin serum at lower part of septum of nose. It remained stationary for two years, when discharge became more consistent, and a scab formed, and since that time superficial ulceration and scabbing have been spreading, till now the tip also, and septum of the nose, are involved. The scabs are of a yellowish-green colour, and on separating, leave the subjacent parts in a state of ulceration. About 12 months ago, small papulæ formed upon left cheek; they discharged from their summits thin purulent matter, which concreted into scabs of the same character as those on nose. About nine months since a similar eruption appeared on each side of neck, and there is now a stripe of superficial ulceration, covered with green scabs, extending from lobe of ear downwards to near clavicle. Right cheek became affected six weeks ago.

Back of neck is swollen, and indurated from about the 3d to the 7th vertebra, swelling extending the whole breadth of neck. It is attributable, apparently, to the irritation of a seton inserted in May last, and followed by an attack of erysipelas.

General health not much affected; catamenia absent for nine months. Was a patient in this house in May and June last, when Nitr. Argenti, and other local applications, were of little service, the cure being apparently affected by the attack of erysipelas.

R̄ Iodid. Plumb. 3j.; Axungiæ, 3j. M.
F. unguent maculis impetiginosis adhibendum.

Sum. Iodid. Amyl. ʒss. ter indies.

April 28th.—Dismissed, considerably improved.

Cancer.

A very complete trial was made of the hydriodic acid in a case of cancer of the mamma, but unfortunately with no other result than that which has hitherto followed every attempt to find a remedy for that terrible disease. It is needless

to insert the case at length. The woman was 40 years of age, and the tumor of 3 years' standing. She came into the hospital for the purpose of having it removed. The operation was prevented by an attack of erysipelas, which came on the very day fixed for performing the operation. On the subsidence of the erysipelas, several lymphatic vessels were found, hardened like whip-cord, and an enlarged gland above the clavicle. All thoughts of excision were therefore abandoned, and the patient put upon the liquid hydriodic acid. It should have been mentioned in the former part of this paper, that the strength of this liquid acid is exactly the same as that of Coindet's tincture of iodine, if, in preparing the latter, the quantity of alcohol be determined, as I believe is commonly done, not by weight, but by measure. In that case an ounce of either preparation contains ʒij. of iodine. Of the liquid acid the patient took ʒss. three times a day, equivalent to 3j. of iodine, commencing on the 13th February, and continuing without any intermission till 26th March.

She took, therefore, in all, upwards of ʒv. of iodine. The effects of this very large quantity upon her complaint may be judged of, from the report made on the day the medicine was intermitted.

March 26th.—Has used hydriodic acid since last report; no change in glands of axilla, and above clavicle. Tumor of mamma larger, and ulceration deeper, more extensive, and very foul. Little change in pain, though for the last two days it has been aggravated. Pulse 84; general health pretty good. Dismissed, with advice.

Tumors.

Mrs. Gibson, æt. 34. August 8th: Seven months ago, leg became affected with considerable pain and erysipelatous redness; this shortly afterwards subsided, and upper part of leg began to swell: since then it has gradually increased to present size.

On admission, calf of leg measures two inches more than opposite one in circumference. On internal side it is pretty hard, and unyielding; at external part it is soft and elastic, but no fluctuation can be recognized in it. Tumor is somewhat, though not very, moveable; seems to arise deep among the muscles, and does not appear to be attached to

any of the bones. Says it is the seat of constant pain, sometimes lancinating.

Dismissed cured.

This patient was put upon gr. xv. of the iodide of potassium daily, and directed to rub frequently the leg with an ointment containing the same medicine, and to abstain from motion. Under these means the swelling gradually disappeared; and when she left the hospital on the 2d October, there was no vestige of it remaining.

Nothing could be more unexpected than the issue of this case, and it excited much surprise in all who witnessed it. The fact that at a consultation, held after her admission, several of the gentlemen were of opinion that the limb would ultimately require amputation, shows that the tumor was one of no trifling description.

It is right, however, also to mention, that the cure was not permanent, as will be seen from the following report, taken on the readmission of the patient into the hospital on the 20th December. This report I insert, as marking the peculiar nature of the disease, as upon that peculiarity, there can be little doubt, depended altogether the efficacy of the remedies employed.

Dec. 20th.—Leg continued free from swelling and pain for about a month after dismissal. About this time, after exposure to cold, began to experience lancinating pains in the part formerly affected, which became soon after swollen, and gradually increased to the same size as at former admission. Continued the iodine for some time after being dismissed; but she has undergone no treatment for the last six weeks. Being at present in the ninth month of pregnancy, she is dismissed with advice till after delivery.

Lepra and Psoriasis.

John M'Lellan, ætat. 32, labourer. Jan. 17th: Extremities are the seat of a scaly eruption, which commenced about two years ago around knees and elbows, in the form of roundish patches, slightly elevated, and surmounted by shining white scales. These have now coalesced into large blotches, rough, red, and scaly, with occasional small fissures scattered through them. Experiences no uneasiness from complaint. General health good.

Sum. Iodid. Amyl. ʒss. ter indies.

Jan. 24th.—Spots on skin somewhat

less red and scaly. Iodine does not produce costiveness, and in other respects agrees well.

Augeatur dosis ad ʒj.

Feb. 23d. — Patches on arms and trunk gone for some time, and natural texture of skin restored. Still a little redness, and some vestiges of spots on lower limbs. Has taken since the 18th ult., ʒxcvi. of the iodide of starch, equivalent to ʒiv. 3vi. gr. xxiv., or 2304 gr. of iodine. The medicine gave the usual tinge to the secretions, but did not produce costiveness, nor any other inconvenience.

Feb. 26th.—Dismissed cured.

In another case of psoriasis some benefit was derived from the iodine, but it was by no means so marked as in the preceding case. A full trial of it was not made, as the patient was remitted to the physician on my ceasing to take charge of the surgical wards, in May last. In the case of Purdie, (ward No. 8.) admitted for an ulcer of the leg, but also affected with lepra of twelve years' standing, the iodine appeared to be of service. She commenced the use of the iodide of starch in the dose of ʒss. three times a day on the 12th January, and on the 13th February the eruption was nearly gone. But as the disease usually got better in the spring, the amendment may have been owing to the season as much as to the remedy. I may further mention, that in a case of lepra which I treated in private with the iodide of starch, in the dose of a tea-spoonful three times a day, a cure was effected in about six weeks.

Ichthyosis.

Donald M'Donald, æt. 19, shoemaker.—Nine days ago, and three after impure connexion, observed some small pustules on glans; they were at the time productive of no uneasiness, and were in consequence neglected. Five days ago, after a debauch, observed prepuce to be swollen and painful, and next day complete phymosis came on. Swelling gradually extended upwards, till the whole penis became affected. On admission, swelling is so great, that glans cannot be uncovered. Penis is of dusky red, and prepuce is beginning to assume a livid appearance at its upper part. Glands in groin are very slightly enlarged; some fever; pulse 90; tongue white.

Whole body, but particularly front of

thighs and legs, is the seat of a scaly eruption. Scales on thighs and knees are small, thick, of a greenish colour, and closely set, somewhat resembling shagreen in appearance; in other places they are large, thin, and light coloured. On desquamating, skin is left rough and tender. This eruption he avers appeared three days after connexion. Denies previous infection. Has been using mercury for the last four days, and his mouth is slightly affected.

Circundetur penis cataplasmate.

Utatur Mistura emeto-cathartica m. s.

March 12th, day after admission, fore part of prepuce gave way by sloughing, and glans protruded through opening. Fore part of prepuce removed by knife, and leeches applied to penis, with barm poultice. Sloughing quite stopped, cut surface having a healthy aspect. General excoriation of surface of glans, and one small elevated sore; no discharge from urethra; skin as at admission.

Sum. Iodid. Amyl. ℥ss. ter indices.

15th.—Medicine agrees well.

Augment. dosis ad. ℥j.

25th.—Wound from circumcision now healed. Still superficial ulceration of glans, to which solution of Nitr. Argenti has been applied. Scabs on limbs somewhat less dense. Iodine agrees well, and urine deeply tinged.

Utatur Baln. Calid. Calore grad. 110 ad 120.

26th.—Could not endure bath hotter than 105°. Neither in perspiration from forehead, nor in water of bath, could any iodine be detected.

April 28th.—Skin now well; penis completely cicatrized. Dismissed cured.

It is necessary to state, with respect to this patient, that he came into the hospital for the venereal affection first described, and that no reliance can be placed on the very improbable account given of the origin of his cutaneous disease, as he spoke and understood English very imperfectly, and varied in his statements every time he was interrogated.

I conclude the subject of cutaneous diseases by saying that, in a case of impetigo sparsa, a cure was effected under the use of the liquid hydriodic acid, internally, and the citron ointment as an external application, and that no benefit was derived from the iodide of starch in a very obstinate case of porrigo favosa.

HOMŒOPATHY UNPHILOSOPHICAL AND QUACKISH.

To the Editor of the Medical Gazette.

SIR,

THE essence of the inductive philosophy of Lord Bacon has been truly said to consist in *ascertaining the universality of a fact*. This was the method which this illustrious philosopher,

"The great deliverer, he from whom the gloom
Of cloistered monks, and jargon-teaching schools,
Led forth the true philosophy,"

recommended us to pursue in our inquiries after truth. Prior to his time, the logic of Aristotle held an usurped dominion over the kingdom of science, and the syllogism was universally considered a tribunal, from whose decisions there could be no appeal.

All the errors which have crept into science—all the false conclusions which have been deduced from the investigations of particular branches of knowledge—have originated in a neglect of the important rules laid down by the author of the *Novum Organum*. There is not a more remarkable instance on record of the folly of generalizing from a few particulars, than that exhibited by Hahnemann and his followers. From the examination of a few insignificant facts as the basis, they have created a mighty superstructure, which is designated by them, with pomp and parade, "the science of homœopathy!"

If the principle which the homœopaths consider to be unequivocally established be founded on a logical deduction from admitted premises, the whole system of medical treatment adopted by "allopathists" must be founded in error. Once admit the truth of the homœopathic theory, and the science of medicine must undergo a revolution!

Before I consent to remodel the whole fabric of medicine, and to abandon the principles which I have been taught to consider to be founded on a correct view of the character of disease, I naturally ask myself a few questions. In the first place, is such a medical change necessary? Is our present system, as taught in the schools, so grossly imperfect as to require such a thorough regeneration as the homœopaths would lead us to believe? Every practitioner must admit that there are diseases which frequently baffle the united skill of physician, surgeon, and apothecary, and

that the science of medicine, as at present established, is justly called an "*uncertain*" science, and this uncertainty must exist, so long as medical men have to deal with *living* beings. If the homœopathsists can make medicine an *exact* science, and can point out to me a more successful mode of treating those diseases which are considered by us, under certain circumstances, as incurable, I will willingly consent to throw aside all my preconceived ideas, and confess myself a proselyte to homœopathy. If I am travelling one road to a certain point, and a man comes up to me and recommends me to change my route, I naturally ask him to point out to me the advantages which I am to derive from the change?—if there are none, I prefer following the dictates of my own judgment. What has been said by Paley of religion, may not inaptly be applied to physic. A man is at liberty to think as he pleases on the subject of religion; but he ought not to be allowed, by the magistrate, to teach to others doctrines at variance with the established creed of the land, and inimical to the divine word of God.

With regard to physic, Morison, Eady, and the Homœopathsists, may imagine they have discovered a "royal" and a *rail-road* to health; but they are not at liberty to compel others to travel this road, when it is certain it will tend to their destruction.

Government ought to have it in their power to put a stop to the practice of men, when that practice can be proved to be detrimental to the public good.

In the case of the much-lamented death of Madame Malibran, as you justly observe, the treatment adopted during one short hour, in her precarious state, may have made the difference between life and death. The danger arising from the practice of homœopathy is similar to what is likely to accrue from any other description of quackery. It is not that there is any thing pernicious in the medicines they administer, but the evil lies, as Sir Gilbert Blane observes, *in the false confidence which is inspired, to the exclusion of other and better remedies* *. I speak, sir, from personal observation of the evils resulting from their tampering with the life of a fellow creature. Not many months ago, I was called in to a serious case of inflammatory disease, in consultation

with a gentleman who was treating the case homœopathically. It was not long ere I perceived that the patient's life was in jeopardy, and I feel assured, that if active remedies had not been had recourse to, the patient would have been lost.

A practitioner is called in to a serious case of enteritis; carrying out the homœopathic principle, arsenic and powerful stimuli ought to be administered, because, when these medicinals are taken in a state of health, symptoms similar to those arising from intestinal inflammation are produced! "*Similia similibus curantur*," say the homœopathsists. Need I say what would be the consequence of this treatment?—death, as a matter of course, in ninety-nine cases in a hundred.

I will suppose another case:—A man has taken arsenic, or laudanum, for the purpose of putting an end to his existence, and stupor, or acute gastric inflammation, is the consequence. If the homœopathsists practised the doctrines they taught, they would administer small doses of the *very drug with which the patient had been poisoned*!

Iodine I have found to be almost a specific in certain cases of secondary syphilis, and in a variety of cutaneous affections; but I never yet saw symptoms resembling, in the remotest degree, syphilis, arise from the exhibition of iodine to a person with an indurated liver.

In opposing homœopathy, I would not run into the opposite extreme, and consider the beneficial effects of a medicine to increase in a ratio with its dose; neither will my credulity allow me to believe that a *millionth* part of a grain of calomel, given every two hours, will impede the disorganizing progress of an acute attack of *iritis*: the idea is preposterous!

I cannot bring myself to believe that these practitioners act up to their own principles. They may *talk* and write about their surprising cures, and persuade the credulous that they were treated homœopathically, but it is my firm conviction, that, should one of these practitioners be attacked with inflammation of the brain, or by any other serious organic disease, he would quickly abandon his own crude notions, and submit himself to the ordinary mode of treatment. This is the best mode of testing a man's belief in a particular doctrine. It may be said that a man

* Medical Logic.

may "know the right, and yet the wrong pursue," and that he may preach, and yet not have the moral courage to *practise*; but he who knows any thing of disease, will not, if life be sweet to him, trifle with himself by neglecting the surest mode of arresting its progress.

I remain, sir,
Your obedient servant,
FORBES WINSLOW,
Member of the Royal College of
Surgeons, London.

45, Hertford-street, May Fair,
Oct. 8, 1836.

CASE OF POISONING BY FISH.

By HENRY BULLOCK, M.R.C.S.

ELEANOR MERWICK, ætat. 39, of good general health, partook, in common with her family, at dinner, of muscles, which had nothing peculiar either in their smell, taste, or general appearance, at one o'clock, on Thursday, September 22, 1836. Her account is, that having eaten about a dozen, she, in about a quarter of an hour after, experienced great uneasiness, and a sense of weight at the epigastrium, which continued increasing for about an hour, when a sensation of numbness and tightness of the surface generally supervened, immediately followed by the formation of large, red, and white prominent patches upon various parts of the body, accompanied by an intolerable itching and a very tormenting heat, while the eye-lids and face were enormously swollen and red. Two hours having elapsed, and the intensity of the preceding symptoms rather increasing than diminishing, she was seized with a violent suffocating dryness of the throat, and with oppression at the chest, attended with the most urgent dyspnoea; her eyes were also suffused and discharging copiously, and she complained of cramp in the calves of the legs. About this time I saw her, when the pulse was rapid and the tongue crimson, whilst her body was literally covered by this violent form of urticaria, so that she appeared to be suffering the most extreme agony. I directed her immediately to drink largely of milk, and to repeat it at short intervals. In about an hour the symptoms began to abate, the heat and irritation of the skin first subsiding; the

breathing was next relieved, and all the symptoms gradually and rapidly disappeared, so that at seven o'clock, after having slept half an hour, she awoke, being perfectly well, and has continued so ever since. It is to be remarked that this woman was the only one of the party who suffered from the effects of the meal, and that she had experienced a similar attack twelve months since, after eating muscles.

In this case, it would appear that the poisonous effects of the muscles arose from idiosyncrasy, since the patient had previously suffered a similar attack from the same exciting cause; also from the remainder of her family having eaten of the same food with perfect impunity. The treatment adopted was that usually pursued at St. Thomas's Hospital with universal success.

Möhring *De Mytilorum*, &c. has related several cases precisely similar to the above, with one exception, namely, that the chest symptoms preceded the cutaneous irritation, and all his patients recovered under the use of emetics, which appears to be the practice recommended by Beck, and most authors. A number of cases, however, are recorded in the *Gazette de Santé*, relieved by æther, the eruption having given place to the most urgent asthma. Dr. Dulong has also given æther, but in his case slight mention only is made of a very temporary and partial eruption, with swelling of the eye-lids and face. The asthma was distressing.

From the reported cases in which æther has been employed, and from what we know of its action upon the system, it would appear applicable only at a later period of the disease, and in those cases in which the dyspnoea is the most prominent feature.

The treatment by milk exemplifies the efficacy of a remedy, the mildest, perhaps, employed in medicine, and peculiarly successful, at the same time possessing many advantages in these cases, over the use of emetics, both as it greatly shortens the duration of the disease, and consequently the anxiety and physical sufferings of the patient. It is perhaps difficult to explain the *modus operandi* of this remedy. Is it not highly probable that the irritating matter in the stomach combines with the milk in coagulating, and that in consequence of this chemical change it

is rendered insoluble, and hence becomes innocuous, in a manner somewhat analogous to the action of albumen on corrosive sublimate?

St. Thomas's Hospital,
Oct. 10, 1836.

**PHYSIOLOGY OF THE NERVES
AND MUSCLES OF THE
EYE-BALL.**

To the Editor of the Medical Gazette.

SIR,

THE polite manner in which Mr. Hunt accuses me of literary dishonesty, and the courteous terms in which he charges me with a want of courtesy, must have a powerful effect in restraining me from any undue severity in my remarks upon his letter, dated Sept. 26.

It will be well known to many of the readers of the *MEDICAL GAZETTE*, that I have, on several occasions, addressed them on the subject of the nerves of the face and of the eye: more recently my attention has been directed to the nerves of the eye-ball in particular. With respect to the paper which was read at the late meeting of the British Association, the object of it was to give what I hoped would be considered a complete explanation of the physiology of the nerves and muscles of the eye-ball, which I believed had not hitherto been done. With that object in view, I was anxious to ascertain what was the precise condition of the state of our knowledge on this subject up to the present period. In so doing, I gave a brief abstract of all that I knew, and mentioned the various views and opinions of different individuals, as far as my knowledge extended; pretending to have discovered nothing myself, but simply endeavouring to draw conclusions from these various sources that should be rational and satisfactory.

In the course of my inquiry, I thought it right to mention a view which had been promulgated by Mr. Hunt, and which I regarded as a very rational view, otherwise I should certainly not have brought it forward as I have done. This view of Mr. Hunt's, however, I could not consider but as still leaving the matter far from being settled, and very imperfect. So far as adopting that solitary view goes, my

explanation accords with Mr. Hunt's, but no farther; and that view I have attributed to him in, what I thought, very distinct terms. What were the words which I made use of?—"I cannot close this paper without observing that my colleague, Mr. Hunt, first suggested the probability that the complexity of the nerves of the orbit was connected with the varied motions of the two eyes which I have pointed out." Who, that reads the foregoing paragraph, can doubt "whether (in Mr. Hunt's words) Mr. Walker has made sufficient acknowledgment of the use he has made of the discoveries" of Mr. Hunt? Discoveries!—what has Mr. H. discovered? Did he discover the oblique muscles, or the fourth and sixth pairs of nerves?—or does he pretend to have discovered, that, when we look at an object laterally, one eye is turned inwards and the other outwards? If he does, he may rest assured that no one, either in or out of the profession, will ever acknowledge any such claims. Mr. Hunt has the merit of being the first to suggest what I have above attributed to him, and that is all that he can lay claim to; and it has been willingly and properly acceded to him.

It may suit Mr. Hunt's purpose to say that my views are similar to his "with one exception, viz. the action of the superior oblique muscle." Mr. Hunt very well knows, however, that there is something more than this: he knows that some important conclusions were drawn relative to the fourth nerve; that the superior oblique was considered as the antagonist of the external rectus in one eye; and that these muscles were associated in the action of the two eyes, when directed laterally. In short, if Mr. Hunt had said that my views were *dissimilar* to his, "with one exception," &c., he would then have stated exactly what is the case.

Mr. Hunt, to the best of my recollection, not only argued that the superior oblique turned the eye outwards and downwards, but farther, that he was the *discoverer* of this action. Whether he still reckons this as one of his discoveries, I know not; I only know that it was first suggested by Albinus, and is now maintained by Sir Charles Bell and many others. So far from Mr. Hunt's view settling this question, indeed, I do not believe that he offers a single reason for the fact, that the super-

rior oblique has a separate nerve as well as the external rectus.

Having thus, as I trust, fully answered the charge of appropriating Mr. Hunt's discoveries, I will proceed to make a remark or two on his other accusation—of want of courtesy. Does Mr. H. consider that, because he, two years ago, offered a suggestion in his introductory lecture, and last year read a paper before the Medical Society, in which he repeated the suggestion—does he suppose that the subject of the physiology of the muscles and nerves of the eye-ball is therefore to be laid under a ban, to be tabooed, and that no one must approach it until he repeats the suggestion in some other form? Was it not sufficiently published by being delivered in a public lecture-room, and proclaimed to a meeting of a public society, for me to allude to in reading a paper before another society, or in another lecture-room? That it has been published at this time in the *MEDICAL GAZETTE*, Mr. Hunt may thank himself: it was owing to the representations he thought proper to make amongst the profession here, that I was induced to request you to give it a place in your columns, in order that the profession might judge for themselves whether or not I had done an act of injustice, and with them I willingly leave it for decision.—I have the honour to be, sir,

Your very obedient servant,

JOHN WALKER.

Manchester, Oct. 4, 1836.

ANALYSES AND NOTICES OF BOOKS.

“L'Auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

The Human Brain: its Configuration, Structure, Development, and Physiology; illustrated by references to the Nervous System in the lower orders of Animals. By SAMUEL SOLLY, Lecturer on Anatomy and Physiology in St. Thomas's Hospital, &c. &c. With Twelve Plates.

THE title of this book amply points out the nature of its contents. The subjects embraced in it are of wide extent, and include some of the most obscure questions in physiology; we may add, that

they have been treated by Mr. Solly in a manner that reflects the highest credit upon his industry and talents. He has presented us with an useful summary of the most valuable results that have been recently obtained by the several anatomists and physiologists, at home and abroad, who have cultivated this subject; this by itself is an acceptable offering to the profession, but we have besides numerous important observations of the author's own, both on the structure and physiology of the brain.

When we cast even a cursory glance over the names of the writers whom Mr. Solly is called upon to quote, we cannot but perceive that it is essentially a new department of physiology of which he treats,—that it is one which has risen up as a distinct inquiry in the present day. So long as it was considered that the brain itself was the primary part to be investigated, and that it was the source of a nervous power common as regards the nerves of the body, no progress could be made; but when it was announced that a certain series of nerves, arising from a particular tract of the brain, were endowed with properties perfectly distinct in their nature from another series arising from a different tract, then the investigation assumed a new character. It is obvious what the next step in the progress must be. As the tracts of nervous matter prolonged from the brain, or towards the brain, were proved to give origin to nerves possessing distinct endowments, the inference was drawn, that these tracts themselves must likewise be distinct in their nature from each other. Hence the chief objects of interest became, on the one hand, to ascertain with accuracy the proper functions of the several nerves, by observing the organs which they supplied by judicious experiments; and, on the other hand, to trace through the brain the columns of nervous matter with which they were connected at their roots. By these means, and with the assistance of pathology, which, in a subject like this, may be regarded as taking the place of experiment, it was reasonable to expect that we might acquire some distinct knowledge of the uses of the parts situated deeply in the brain. Comparative anatomy would also lend us most valuable assistance. But it is obvious that the foundation of all reasoning on the func-

tions of the tracts in the brain, must be a correct knowledge of the particular uses of the nerves which arise in groups or in succession from the different subdivisions of the cerebral mass.

Such considerations have led us to examine with peculiar interest that part of Mr. Solly's work which treats of the functions of the individual nerves; and we have been gratified by finding that he presents a very correct account of them. We have also been pleased to perceive a liberal spirit displayed by him in bestowing credit where it is due upon those gentlemen who have contributed most to improve our knowledge on these points. There are some mistakes, however, in regard to those to whom we are indebted for some of the discoveries alluded to. In particular, it has surprised and disappointed us to find no notice taken of the labours of an anatomist who exhibited great zeal and intelligence in prosecuting these inquiries at their commencement;—we allude to the late Mr. John Shaw, whose loss to science, at the time when engaged in those very pursuits, and when he had begun to gain a high reputation, was universally deplored by the profession. By those who will take the trouble of looking back to the numerous papers which this gentleman published on the nervous system, at the first promulgation of the discoveries in question, it will be found that he did much more, by his dissections in human as well as comparative anatomy—by his experiments and his writings—to advance our knowledge of this branch, than any of the persons, with one single exception, whose names it is usual to bring forward as meriting especial distinction. With regard to the roots of the spinal nerves, for example, Mr. John Shaw repeated the experiments which had originally been performed by Sir Charles Bell, confirmed their results, and exhibited them publicly to his class in Great Windmill-Street, two years at least before M. Magendie had thought of putting himself forward as an original experimenter on the nerves.

Mr. Shaw was likewise the author of a paper, which attracted much notice at the time, presenting, among other subjects, a full account of the experiments on the roots of the spinal nerves; and in which paper he anticipated the de-

scription of the same experiments, by M. Magendie, by several months. As this paper was delivered to the Medico-Chirurgical Society, some time elapsed after it was read before its publication; yet, notwithstanding this, it preceded the memoir of M. Magendie. It was entitled, "On Partial Paralysis," and was distinguished from M. Magendie's memoir by other and more important circumstances than merely that of being first before the public. It not only contained, as we have stated, an accurate account of the distinct properties belonging to the anterior and posterior roots of the spinal nerves, and a detailed description of the experiments which established these facts, but it embraced observations of equal interest upon numerous other nerves: for example, it contained proof of the fifth pair of the brain corresponding, in structure and functions, with the spinal nerves, while it showed the distinction between this class of double nerves and the portio dura, the ninth, &c. But Mr. Shaw did not limit himself to the illustration of the natural functions possessed by the nerves alluded to; the subject was, even at that time, so much advanced, that, as the title of the paper indicates, he could give pathological observations in addition, founded upon these new inquiries. These illustrations were of the highest importance. The nature of the questions discussed may be judged of by the title affixed to one of the divisions of the paper, which is this:—"Why should Sensation remain entire in a limb when all Voluntary power over the action of the muscles of the limbs is gone? or why should Muscular power remain when Feeling is gone?" We have only to remark, that the explanation which Mr. Shaw has given of these remarkable occurrences, is as full and satisfactory as any that could be presented at the present day, after sixteen years' acquaintance with the subject. Now when, at a subsequent period, M. Magendie came into the field, and related the same experiments on the spinal nerves as if they were original, he might not have been aware of Mr. Shaw's paper: but what principally astonishes us, is, that M. Magendie should have been adopted as an authority, when his paper evinced most decidedly that he was far behind in his knowledge of the subjects for which he was quoted. Although he presented his

experiments on the roots of the spinal nerves so late, he described them as quite isolated, having no connexion with, and receiving no confirmation from, any others. He does not once refer to the fifth pair as a corresponding nerve that might illustrate their functions, or to the portio dura and ninth pair that might be shown to differ from them. He does not pretend to explain paralysis of any kind from his experiments: indeed he refers to them as so recently performed, that this could not be expected; and so far is he from leading us to suppose that he had ever before succeeded in obtaining the same results, that he acknowledges that he had been baffled in his previous experiments. But there is the strongest reason, independently of all these arguments, for rejecting M. Magendie altogether as an authority upon the experiments in question. If those who quote him had perused his second paper, published only two months after the first, or any of his subsequent publications, they would have seen that he had completely changed his views respecting the functions of the roots of the spinal nerves, and expressed opinions diametrically opposed to those now generally adopted. In his second paper, M. Magendie maintained that neither of the two roots of the spinal nerves is exclusively for motion or sensation—that each of them is compound: that the anterior root, although principally for motion, is subservient also to sensation; and the posterior root, although principally for sensation, is subservient also to motion: that the same root, in short, may transmit an influence outwards to the muscles, to cause muscular contraction, and also convey a sensation inwards. Such are his most matured opinions. But it is to be remarked that, although they are his deliberate opinions, he has never made a single attempt to corroborate them by any experiments besides those on the spinal canal: he has never thought it worth his while to examine whether the same characters belong to the corresponding nerves of the brain or not. Things, indeed, have turned out so extremely favourable to this physiologist, that, as it were, in spite of himself, and by the most singular good fortune, he has enjoyed the reputation of entertaining opinions quite different from those set down in his books. This misrepresentation of his views, instead

of inflicting injury, has contributed to magnify his fame: the misconception as to the real views which he advocates, has been a principal cause why so few authors (M. Müller, of Berlin, we believe, is the only one) have undertaken to controvert them, and show their utter groundlessness!

We may be allowed to give another instance, suggested also by reading the work before us, of an occasion in which Mr. Shaw ought to have been quoted in preference to any other writer, and his authority joined to that of Sir Charles Bell. The points of which we are now treating may perhaps be thought by some to be matters of indifference; but how can medical men be encouraged to prosecute their profession scientifically, if they do not see that their just claims to celebrity will be protected?

When Sir Charles Bell announced in his first paper to the Royal Society, that the fifth pair was the only nerve of the encephalon that resembled the spinal nerves, he founded this opinion upon its being the sole nerve of the brain which had two roots, with a ganglion upon one of them, like those nerves. It was his chief object, in reference to this class of nerves, to prove that from their possessing two roots, of distinct anatomical appearance, they had two different properties—viz. sensation and motion; whilst the other nerves of the brain having only single roots, were endowed with one property alone. We may conjecture that the principal intention of his experiments upon the nerves of the face, was to establish this important position—that the fifth pair, which has a double root, gives both motion and sensation; while the portio dura, which has a single root, gives only motion. This distinction had necessarily to be drawn between these nerves, before any other conclusions could be arrived at regarding them. Now it so happened, that although he announced the fifth pair to be the nerve of sensation, and likewise of motion, to the muscles of mastication, the experiment which he performed to confirm this view of its double functions did not bear him out. It is obvious that he was misled by having a false notion as to the ultimate distribution of part of the motor root; for he affirmed that the infra-orbitary branch conferred motion upon the lips as they are concerned in mastication, but was not further a motor nerve. M. Magen-

die, while repeating these experiments upon the nerves of the face, was the first who exposed this error of putting forward the in'ra-orbitary branch as an example of a part of the fifth pair having the power of motion; and he shewed, on the contrary, that this particular branch had only one of the properties attributed to it by Sir Charles Bell—viz. that of sensation*. He thus destroyed the only experimental proof at that time given of the fifth pair possessing two functions, in virtue of its double root; and it is evident how extremely careless he was, and how little master of the subject, from his not being at all conscious of the serious blow that he had thus inflicted upon the principle which was the very foundation of all the new views on the nervous system. The most important thing at that period to establish or controvert, he might have known was, whether the spinal nerves and fifth pair acquired their distinct powers of motion and sensation in virtue of their double roots; and when he had proved that the only branch of the fifth offered by Sir Charles as an example of the compound nature of the fifth, was not a compound nerve, but a simple one only, was it not strange that he should have let the matter rest at this stage? But such is the fact; and nothing further did he attempt at any subsequent period, either with the view of confirming or invalidating his original statement. Had we relied, therefore, upon this gentleman for deciding what was the true nature of the fifth pair, we might have waited to the present day. He was content, at that time, with leaving it to be supposed that this nerve was for sensation alone, and had no power over the muscles of mastication.

Now it was Mr. John Shaw who rescued the subject from the state of error in which it might have remained, if it had been left to the superintendence of M. Magendie. He selected for experiment a division of the fifth pair, situated more deeply than those branches that had been previously experimented upon, and composed, without doubt, of the two conjoined roots. This was the inferior maxillary division of the fifth;

* "Le resultat que nous avons obtenu s'accorde parfaitement avec celui que nous venons de rapporter, à l'exception toute seule de l'influence de la section de sous orbitaire sur la mastication, influence qui n'a pas été évidente pour moi."—*Journal de Physiologie*, 1821.

and by performing his experiments upon it, he at once set the question at rest between M. Magendie and Sir Charles Bell. When he had succeeded in showing, on the living animal, that this was both a muscular and sensitive nerve, he conclusively proved that the latter gentleman had been correct in his general inference, and that it was a nerve of motion only to the muscles engaged in mastication, and to none others.

We have been led into this discussion by the perusal of the work before us; for here, we contend, was an important fundamental fact in the physiology of the nervous system, established experimentally by Mr. Shaw, when the truth was in imminent danger of being obscured by the experiments of M. Magendie; and for this service we owe both respect and gratitude to his memory.

The first part of Mr. Solly's volume relates to comparative anatomy, in which a succinct, but, as it appears to us, very clear and satisfactory, description is given of the nervous system in different classes of animals, illustrated by numerous engravings. The author then passes on to the human brain and its membranes, and afterwards to the dissection of the cerebrum and spinal cord. The fourth part is occupied by the nerves, and the fifth by the cerebral circulation. The development of the brain, its physiology and pathology, complete the essay; and the whole forms a volume highly creditable to the author and to the school which has the advantage of his services as a teacher.

MEDICAL GAZETTE.

Saturday, October 15, 1836.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

AN HOMŒOPATHIC APOLOGIST.

EVEN as we expected, so has it come to pass. Quackery moves in an orbit well defined and palpable, nor does it require any great astronomer to determine its place at any given moment. The same beaten path has been traversed

for ages: yet, to the unreflecting portion of the community, the common course pursued is as much a mystery as it was to the first observers. Homœopathy, though following Morisonianism in quick succession, and in a very analogous career, will still, no doubt, dupe some people: nor will the similarity between the passive destructiveness of the one, and the manslaughtering tendency of the other, be speedily perceived. But dear-bought experience will most likely remove the veil at last.

We pointed out the benefits which even the death of Malibran would be sure to confer on the homœopaths: their mystery would be talked of, and at least their existence would obtain publicity. It was natural too, to suppose that their chiefs (if they had any such in this country) would stand forth in defence, and take up the cause with promptitude and vigour. We suspected, however, that the means of doing this were wanting; that their powers in the field of literature were, like their doses of medicine, infinitesimally small, and only likely to operate, if at all, through the effects of the imagination. Nor have we been deceived, or disappointed. The doughty champion who has stepped forward to advocate the principles of the old physician of Dessau, is the famous Dr. Uwins, who, though "striking too short at Greeks," has ventured to take homœopathy under his feeble protection.

There would be nothing offensive in this little display of zeal — for new converts are always celebrated for their activity—had the Doctor only shown some spirit of fair dealing in his proceedings; but in taking up the cause of Hahnemannism, and failing to get a hearing for his controversial denunciations, he fastens, with a despairing tenacity, on an individual whom he supposes, or affects to suppose, to be an assailant of his.

In a letter to the *Times*, Dr. Uwins undertakes to defend himself from what

he conceives to be an attack on him in this journal; and he pretends to have discovered the author, whom he mentions by name—Dr. James Johnson. How blind do angry feelings make a man! We believe there is not an individual connected with the medical profession in this country, save Dr. Uwins himself, who would have made so silly a blunder. He has had, it appears, what he calls "battles of brains," with Dr. J. Johnson, at some of the medical societies; and having come off smarting, probably, or only second best, fancies he detects in every opponent of his newly-adopted system, his quondam antagonist. Hence, on finding homœopathy treated with a becoming severity in the *MEDICAL GAZETTE*, his short-sighted spite leads him to imagine that the Editor of this journal can be no other than Dr. James Johnson!

But, after all, what does this amount to? How miserable and contemptible must the advocates of a (so-called) system be, who have none except poor Dr. Uwins to set in the fore-front of the battle; he, too, having no resource, save, in the absence of argument, to attempt personal invective!

His object, however, has, no doubt, been attained. He has had the opportunity, as we guessed that he or some of his brother Hahnemannians would be delighted to have, of advertising himself in connexion with the *new* doctrines. But so it has been with the Doctor on other occasions, and so, no doubt, it will be again. As it was the reflection that "allopathic carriages were in the market at a large discount," which operated so powerfully in inducing him to see what was in homœopathy, so we shall not be surprised, ere long, consistently with his usual choppings and changes, to find him in the ranks of the Hygeists—and then let the Lynches, and Morison himself, look to the supremacy. The Doctor is a facetious man, and can easily write upon any doctrine with that sort

of point which so finely finishes off his letter in the *Times*; "Dr. Hahnemann, against whom? Dr. Cullen—Hoffman—Gregory? No, against Dr. J. Johnson!! *Risus*, indeed." *Risum teneatis?* say we; and it is all we can find breath to say—for surely the Doctor will be the death of us!

MEDICAL EVIDENCE IN A CASE OF ALLEGED INFANTICIDE.

It is with some hesitation we make the following extract. But we shall abstain from comment, partly because it is scarcely necessary, as the inconsistency which we would expose must be sufficiently palpable to the reader, and partly because we do not wish to assume as correct a report which, in its present state, can reflect so little credit on the medical witness. We have already, on several occasions, endeavoured to point out the propriety of medical gentlemen, who give their testimony in public, taking care that the opinions attributed to them in the newspapers be correctly stated. If they cannot easily effect this, the professional journals are open to them to save them from injustice. In the present instance we think some explanation would be expedient, in order to reconcile, or to set right, the obvious absurdities and contradictions which have appeared in the most widely circulated, and, we should add, trustworthy, of our public vehicles of intelligence.

The *Times* of October 12th contains an account of a coroner's inquest, on the body of a new-born child, supposed to have been murdered. A verdict of "Wilful Murder" was returned against the father and mother. The medical evidence was as follows:—

Mr. Thomas Porter, surgeon, 145, Bishopsgate-Street, stated, that the mother said she heard the child cry. Witness examined the body, which presented the well-formed appearance of a full-grown child, and the chest was well filled. The lungs bore the usual appearance of having been distended

with atmospheric air, which would not have been the case had the child not breathed. *There were no appearances to account for death. He could not say that it died of suffocation, nor that it had not.* The lips were slightly livid. He could not give a decided opinion of the cause of death. It might have died from natural causes before being put into the cesspool, as from not having proper assistance; but witness could not say whether death was the effect of natural causes or of violence.

By a Juror.—The child *might have been drowned* before being put into the cesspool.

Mr. Porter afterwards observed on the probability that the child *was suffocated as soon as born.*

ADVANTAGES OF SMALL HOSPITALS;

OR, CERTIFICATES *versus* KNOWLEDGE.

IN controversial writing, nothing is more satisfactory than to find your opponent proving the accuracy of what you have advanced, even at the very moment he is attempting its refutation. Thus the Editor of the *Lancet*, working in his vocation, opens the flood-gates of his abuse against us, for representing the North London Hospital as a small one, and then, with the utmost *naïveté*, he adds, "*the pupils will soon far exceed the number of those who can be adequately accommodated.*" Now this admission, coming from such a quarter, convinces us of what we had previously heard—namely, that between the smallness of the wards and the numbers who are crowded into them, many students can literally see nothing but the heads and shoulders of those before them.

Again: we reprobated the practice of taking a fee for attendance on both the medical and surgical practice together, on the ground that the pupil could not possibly give his mind to such a multiplicity of subjects. Here, too, our worthy contemporary steps forward in corroboration of our statements:—"The amount (says he) of facts for observation and reflection, always within the walls of the hospital, must invariably be greater

than the mind of any student can grasp and control." Rather a slip, that, eh! Master Wakley; and yet you are so much a friend to the "certificate system," (provided it be practised in Gower-street,) that you approve of and commend an arrangement which solemnly certifies to that having been done which you thus admit no student is capable of doing!!!

The fact is, that in his anxiety to fulfil the business of his vocation, there is no contradiction in terms—no misrepresentation (for an instance see next page), and no abandonment of his own professed principles, into which he is not betrayed. The object is to throw dust in the eyes of the public, and particularly of pupils and their friends, by putting forward the *cheapness* of the North London Hospital, to hide the *dearness* of University College. And we regret to add, that those connected with the School have not thought it beneath them to do the same. We challenge any one of them to tell us why else the advertisements which emanate from University College, *invariably announce the hospital fees, and as invariably suppress those of the medical school attached to it?*—We pause for a reply.

But while we have demonstrated in former numbers that the education, taking lectures and clinical practice together, is considerably more expensive than at most of the large hospitals, we deny that the "North London," by itself, is cheap—if the object be to learn. It is cheap only where the party limits his views to the price at which a certificate may be purchased, of having done that which the patron (we fear we may not add Saint) of the hospital informs us is beyond the grasp "of any student."

We call upon the College of Surgeons, and the Society of Apothecaries, to look to this: it is their bounden duty to refuse those certificates which include medical and surgical practice simulta-

neously; and this, too, at a time when the student is overwhelmed with lectures. Such an idea only requires to be brought before any intelligent person to be scouted; and yet this "certificate system" is practised in Gower-street, and approved by one who professes to be the enemy of every abuse!

But not only does our consistent Editor back up this disreputable proceeding; he goes farther, and argues in favour of small hospitals, as if they were actually superior to large ones! And how does the reader conjecture this is done? Why, by adducing the names of certain distinguished foreigners, who were physicians or surgeons of small hospitals. Thus, because Scarpa and Richter, after many years of labour in but a limited field of observation, attained important results; therefore they would not have made the same advancement if their means of investigation had been more extensive! Blockhead! he does not see that the minds of such men overcome the disadvantages under which they are placed; and that their genius shines forth, not in consequence of their hospitals being small, but in spite of it.

Besides, what parallelism is there between two or three instances of men becoming distinguished after many years of the most assiduous observation and study at hospitals of small size, and the education of young gentlemen who have but a short time to devote to clinical attendance, and for whom it is therefore of the greatest importance to witness disease in such varied forms as may render them familiar with its multifarious aspects, before they engage in the responsible duties of their profession. Who but a special pleader would compare things so utterly dissimilar?—who but a hack, driven on by the spur of his party, would plunge into such palpable and stupid contradictions?

As to the *honourable* member's abuse

of the MEDICAL GAZETTE, it is very natural; for, to say truth, we have been rather a sharp thorn in his side.

ANOTHER gross instance of that kind of literary fraud with which we have so often occasion to stigmatize our dishonest contemporary, occurs in the Lancet of this day (Oct. 15th.) In the GAZETTE of October 1, in reference to his puffing of the North London Hospital, and hatred of all others, we said—"the trick is perfectly well understood about town, and is only adapted to catch the novices who are very fresh and green from the country." Now Mr. Wakley separates this entirely from the context, alters the typography, and, wholly omitting its application as a caution against his own knavery, gives it as a general description of "the medical students of the present session" applied to them by the Medical Gazette. *This is false.* But we repeat, that his trickery and his motives are so well known here, that no student who had been even a few weeks in London would incur any risk of being taken in by them; and we believe we may add, that, thanks to this journal, there are now very few in any part of the country who are such "novices" as he evidently takes them to be.

THE LANCET'S PUFFING OF THE GOWER-STREET HOSPITAL.

To the Editor of the Medical Gazette.

SIR,

A LETTER, of which the under-written is a copy, was sent to the Editor of the Lancet two weeks ago, and has been left unnoticed by that very impartial journalist: perhaps you may think it and the inclosed worthy of a place in your GAZETTE; if so, you will greatly oblige, sir,

Your obedient servant,
GUYENSIS.

October 11, 1836.

To the Editor of the Lancet.

SIR,—In drawing up your Comparative Table of Fees for Medical and Surgical Hospital Practice, I am sorry to observe that you have departed from your usual candid and impartial manner of noticing the various hospitals and schools of medicine in this metropolis, and that instead of allowing the student, as heretofore, to exercise his own unbiassed opinion in the choice of a school in which to prosecute his studies, you have thrown a heavy weight into the scale in favour of the North London Hospital. You say that this hospital is the cheapest. Now, sir, the number of beds in the North London Hospital, is, or was, 120; and for these the pupil's fee, for twelve months' medical and surgical practice, is 21*l.* At Guy's Hospital, the medical and surgical beds amount to 540, and the surgical beds of St. Thomas's, which are also free to the Guy's students, to 300, making, in all, 870 beds; and for these the fee is 41*l.* 2*s.* A very simple rule will show which is the cheapest.

The manner, too, in which you have conferred the puff oblique on Mr. Liston, is by no means what we might expect from the Lancet; a work which has all along decried puffing in every shape. This gentle side-wind for Mr. Liston, and the more direct blast of the 'Toronto Licentiate, are from the same quarter of the compass—if not from the same point.

Yours,

GUYENSIS.

P.S.—I rely upon your candour for the insertion of these remarks.

September 27, 1836.

To the Editor of the Lancet.

SIR,

WHEN I found it necessary to conclude my last letter to you by remarking, that for its insertion I must rely upon your candour, I evidently hinted at the reception which I supposed you would give it, and anticipated your refusal to insert it. You have not disappointed me. There was a time when such a letter would have been thankfully received; and had I not known that the affected liberality of the Lancet had long ago given place to an open avowal of favoritism, I should have appealed neither to your candour or sincerity.

In this opinion I am by no means singular; your characteristic generosity is now pretty well understood; and when you had arrived at a certain degree of notoriety by moderate and plausible means,

you thought it would be advantageous to try the other side of the question. I need not tell you that you have been deceived: he who makes it the whole study of his life to deceive the world, will one day become cunning enough to deceive himself; and such is now your case. You began in deceit, and have finished in shame. You decried puffing, and have now become the veriest puff-maker that ever evaded the stamp duty. But was it necessary, in leaving your old friends, to take up with your old enemies? We know your desire for change; but why be-praise and be-laud those whom you have so strenuously condemned? Had your voice been less heard, you might have passed unnoticed; and had your pretensions to impartiality been less, your present turpitude would be overlooked.

Have you so soon forgotten that "the system of election in the institution in Gower-street is in no respect different from that of the most rampantly corrupt medical monopoly in London?" *vide* *Lancet*, August 27, 1836; four weeks from which time you declare the same institution to be the best and cheapest in London. May I ask you what has now become of Stinkomalce? Has it become so buoyant from your inflation as to have risen into those clouds of ignorance which have ever hovered over it since it was built? Be careful, dear sir, in your puffing, or you will one day blow it away. I intend to dip here and there into your last two years' labour, and have no doubt that I shall find a few proofs, such as even you will find it difficult to answer or set aside. Mr. Liston and your other Scotch friends, —of whom, by the by, I wish you joy,— will inform you that facts—

"Are sturdy chiel, that winna ding,
An' dar'na be disputed."

GUYENSIS.

Oct. 11, 1836.

PROPOSED POOR-LAW MEDICAL CLUB AT CAMBERWELL.

To the Editor of the Medical Gazette.

SIR,

As you have given insertion to the anonymous and flowery communication of a "Camberwell Practitioner," you will, I am sure, allow me a brief space for reply in your next number. This champion of medical clubs has made a map of Camberwell to suit his own purpose, and, although he is such a stickler for parishes and districts, he has introduced into his list the names of two gentlemen (Messrs. Flower and Young) who are residing in the

parish of Lambeth. This, I think, needs no comment. But, sir, will this "Camberwell Practitioner" throw off the mask, and enlighten us by his arguments in favour of the system? Can he show us how this innovation will benefit the poor man?—and can he also show that it will not tend to injure and degrade our profession? The most potent argument brought forward by one of the clubbists, at the meeting alluded to, was the following:—"If, gentlemen, you reject this proposal (he should have said mandate), the Poor-Law Commissioners will send young men from the hospitals to take charge of our poor." To what a state are we fallen!

I am, sir,

Yours respectfully,

E. CRISP.

Walworth, October 10, 1836.

[Should the "Camberwell Practitioner" reply to this or the following letter, or both, (as we think he is called upon to do) he must give his name.—ED. GAZ.]

CONDUCT OF THE SUPPORTERS OF THE PROPOSED POOR-LAW CLUB.

To the Editor of the Medical Gazette.

SIR,

PERMIT me, through the medium of your widely circulated journal, to request the "Camberwell Practitioner," who favoured us with an account, in your last number, of the proceedings at the late meeting held in the vestry hall of this parish, to have the goodness to forward his name. I certainly do not think it was exactly right that any remarks made upon the meeting, connected as it was with the interests of every surgeon in Camberwell, should have found a place in your journal, without the author's name. In my opinion, there has not been a more shameful motion started since surgery has been considered a profession. It is not sufficient that Forbes, Bean, Browne, and Flower, have the largest and most respectable practices in Camberwell, but they must concert measures for taking the very bread out of the mouths of the poorer class of surgeons? "After this, pray let us hear no more about the cant of *liberality* and *honour* of the profession," when the above-mentioned gentlemen have condescended to put their names to such an odious piece of business.

By inserting these remarks, you will greatly oblige

Your obedient humble servant,

T. BOWEN, Surgeon, &c.

Southampton-Street,
Camberwell.

**PROJECTED POOR-LAW CLUB AT
CAMBERWELL.**

REPLY FROM MR. HULBERT.

To the Editor of the Medical Gazette.

SIR,

ENGAGEMENTS, and correspondence of a different nature, having so occupied my time as to induce me to delay addressing you until the present occasion, I shall now be more brief than was intended when your last week's number came under my observation; premising also, that I have neither time nor inclination to notice any similar remarks to those which have led to this communication.

Like your correspondent Mr. Crisp, "I feel reluctant" to enter into a controversy respecting the subject upon which we have recently respectively addressed you; but his assertion of being *compelled* to reply to the *misstatements* contained in my letter of the 22d ult. requires me not to pass over the same unnoticed.

How he has been *compelled* to make what every reader of your journal may consider a *voluntary* statement, I am at a loss to determine; unless it has been the result of his acting under the direction of those gentlemen to whose conduct I alluded, and whose opportune and spirited manner of "redeeming the honour of the profession" was assuredly very singular, and may be viewed (by them) as a superior method of supporting professional dignity to the wigs and gold-headed canes of by-gone days. This supposition is strengthened by his concluding paragraph, wherein the important information is given, that "the gentlemen who descended to personalities are prepared to justify themselves for so doing, and to prove the correctness of their statements."

Their method of justifying themselves I must leave to themselves; but their proving the correctness of every statement they made will, in my opinion, be difficult, as I am not without facts of sufficient force to subvert several of the statements made upon that occasion; but to bring them forward will be unnecessary, as the letter in your last number, from "A Camberwell Practitioner," (who is unknown to me) substantiates the correctness of the statement I gave you, and which Mr. Crisp's letter has by no means invalidated.

In conclusion, as Mr. Crisp has expressed a wish that I would "be personal enough to state names," I do assure you that I feel no reluctance in complying with his wish, and will therefore name the following:—Mr. Crisp, Mr. Boddy, Mr. E. Evans, Mr. Hooper, &c.

I consider it unnecessary to make any further comment; and should have

spared myself and your readers this communication, but for the futile charge brought against me, as regards the mis-statements contained in my former letter.

I am, Sir,

Yours very respectfully,

J. F. HULBERT.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE IV.

Further consideration of Age — Boyhood — Puberty — Manhood — Senescence, and Decrepitude. Legal distinctions, and physical and moral peculiarities of each period. Stature and proportion of the Body at Adult Age — Whether the Stature may be determined from the dimensions of a particular part.

HAVING treated in the last lecture of Infancy, or the first period of human life, we shall now proceed to the consideration of the other ages.

Boyhood.

Legal distinctions.—I have already noticed certain epochs belonging to the several periods of life, which are particularly recognized by the laws. The following may be added as specially relating to the age of boyhood or girlhood. An infant of tender years being prosecutrix in a trial for carnal knowledge, the whole of her testimony, recently given, seems admissible, because it is of the highest importance to ascertain the accuracy of her recollection. Under eight, or above sixteen, no infant is to be apprenticed to a chimney-sweeper; or if he be, no settlement is conferred. Before the age of nine no infant is to be bound as a parish apprentice; and children under nine years [3 and 4 Will. IV. c. 103] may not be employed in the factories, except it be in those for the manufacture of silk. The carnal knowledge of a female infant under ten years is a capital offence. To force or decoy away any child under

ten from its parents, or guardians, with intent to deprive such parents, or guardians, or to steal any article about its person, is punishable by transportation, or imprisonment with hard labour: an exception, however, is made in favour of the father of an illegitimate child. Carnal knowledge of a female between ten and twelve, even with consent, is punishable with imprisonment and hard labour. Under thirteen, certain hours of work are prescribed in factories and mills—viz. not on an average more than eight hours a day (excepting in manufactories of silk, where ten hours are allowed). Between thirteen and eighteen, not more than twelve hours' work daily is permitted. Finally, unless great weakness of intellect appear, children are liable to punishment for crimes of commission after the age of seven; but by no means for a rape, or sexual crime, under fourteen.

It must be obvious that these regulations respecting age cannot but sometimes give occasion to inquiries, for the satisfaction of which the services of the medical jurist are necessary.

Physical characters.—The body during this period grows considerably: the limbs lengthen, compared with their previous condition; the voice is sharp, and of much the same volume in both sexes. There is a remarkable disposition for bodily exercise and motion. The milk teeth, or those of the first dentition, have fallen about the commencement of boyhood. The fourth molars make their appearance between the eighth and ninth year, and remain permanent. The incisors, canines, and first and second molars of the second dentition, issue from the gums between ten and eleven, in lieu of the milk teeth, which have disappeared.

Growth of the bones.—The olecranon presents an osseous germ between the seventh and ninth year. The scaphoid bone of the carpus becomes ossified at the same period, and the two osseous points at

the upper extremity of the humerus form a union. At *twelve*, the pisiform body of the carpus ossifies, and there is an osseous point detectable towards the inner margin of the trochlea of the humerus. At *nine*, the three primitive points of the os innominatum, which afterwards constitute the ilium, ischium, and pubis, are found in the lower part of the pelvis. The three bones of the innominatum may still be separated at *thirteen*, but soon after, they become firmly united: an osseous point is found in the lesser tuberosity of the head of the femur, and the neck of the latter bone is now ossified. The cartilages of the larynx are said to become osseous as early as the termination of boyhood,—first the cricoid and thyroid, and then the arytenoid structures: but these changes most usually occur at a much later date.

Puberty.

We now come to that period of life in which great and important changes are wrought in the system. About the age of fourteen in the male, and sometimes earlier in the female, the body begins to present a series of developments which are characteristic. The general growth is remarkable, but especially so that of the generative parts. Of the latter, I shall take occasion to speak more particularly, when treating of sex: at present I confine myself as much as possible to the general developments, physical and moral.

Legal distinctions.—But first let us observe, that there are certain distinctions made by law regarding this age, which merit the attention of the medical jurist. Puberty is, in law, supposed to exist at *fourteen* in males, and at *twelve* in females: which latter supposition seems to be borrowed from the Roman civil law, and to be founded on what is usually observable among females in the East; but it is certainly too early for the generality of the sex among us. Males after *fourteen* may marry, with consent (which is essential up to twenty-one), or by bans not prohibited. Both sexes, between the ages of *fourteen* and *twenty-one*, are liable to be punished for offences of commission, but not for those of omission, save where the liability is specially provided for. They cannot be sued on contracts, except for necessities. The abduction of a female, under *sixteen*, without consent of parents, is a misdemeanor punishable with imprisonment.

I have already mentioned*, that at *seventeen* a male or female may become an executor: I shall now add, that he or she cannot act as such until the age of *twenty*—

one; though, if an infant under *seventeen* be named executor jointly with an adult, he must in an action be joined as a co-plaintiff.

With regard to labour in the factories, under the provisions of the act already referred to [3 and 4 Will. IV. c. 103], no person under the age of *eighteen* is to work at night, or more than twelve hours during the day. There is still a severity in this enactment, as it leaves persons unprotected before they have attained the period of confirmed health and strength, an event which does not usually arrive until about the age of twenty-three.

Physical characters.—The physical changes which occur in both male and female between the fourteenth and twenty-first year, are very remarkable, and characteristic of that particular period of life. But they take place successively, and are diffused over the greater part of the interval. There may, in fact, be marked out an early, a middle, and a final, stage of puberty, during which, beside the development of the sexual apparatus, the following appearances are usually observable. In the male the chest becomes expanded, and the shoulders broader; the voice, hitherto feminine or girlish, first *cracks* (as it is commonly called), and then settles into a steady grave tone; the person begins to be furnished with hair on various parts; and the beard grows, first downy, and then gradually more firm and strong. In the female the breasts become enlarged, and various changes of the person connected with sexual development may be observed. The voice alters likewise, but not to such an extent as in the male. In both there is an enlargement of the capacity of the larynx; but the *rima glottidis*, which in the male increases in size in the proportion of 5 to 10, is augmented in the female only as 5 to 7. The muscular system usually receives large accessions.

But all these characters of the period between fourteen and twenty-one, must be noticed as having an especial relation to sexual development; for where this does not take place, owing to constitutional tardiness, castration, or other obstacles, the boyish character still prevails. Bernt, in his *Sammlung gerichtl. Medicin*, gives an account of a journeyman tailor, twenty-four years of age, who was still a mere boy, puberty having never operated its peculiar changes upon him. And other examples are of no rare occurrence.

Moral peculiarities.—But the effects on the mind are not less remarkable than those on the body. The habits of thought and action, through what Foderé calls “the tyranny of the generative organs,” all undergo a change. The male, who differed as little hitherto in manner as in bodily con-

* MEDICAL GAZETTE, p. 65 present volume.

formation from the female, now becomes more rough and masculine—the female more modest and feminine. It was the *individual*, in fact, who lived hitherto in both sexes; the *species* begins to be developed now.

At the risk of anticipating another part of the course, I am induced to bring to your notice certain peculiarities affecting the female at this period of life, and having essential reference to Forensic medicine. The approach of puberty and menstruation is attended in some females with such a disturbance of the mental faculties, as to raise a question of criminal responsibility. “The crisis of the commencement of the menstrual function,” says Foderé, “is sometimes retarded, and the interference which then occurs produces several alterations in the system—in the cerebral functions more particularly: for a sort of temporary dementia occasionally takes place, the existence, or the possibility of which, may, in certain circumstances, demand the attention of the medical jurist.”

A remarkable instance of this kind occurred not long ago in Sussex. A girl, aged sixteen, set fire to her master's house. She had previously borne a good character, had stolen nothing, and, in short, committed the crime without apparent motive. She was brought to trial at the Lewes assizes. Her master was anxious to save her life; and a gentleman at Brighton, from motives of humanity, undertook her defence. It appeared that she had been a patient in the Chichester Infirmary in the course of the preceding year, when she was afflicted in succession with low fever, measles, scarlatina, and strong symptoms of phthisis. She had never menstruated: had always been of a reserved, taciturn disposition, and had conducted herself in an eccentric manner on several occasions. The counsel argued that under such circumstances, the act for which she was tried, was probably committed in a state of imbecility, or delusion, in which she could not be considered as a morally responsible being. To confirm this view, he called two medical men, Dr. King, of Brighton, and Mr. Pitt, a surgeon, to give their opinion as to the effects which illness, together with the non-appearance of the catamenia, might have on her mind; and whether insanity, under any form or degree, ever happened under such circumstances. The testimony of the medical witnesses was so strongly in favour of this presumption, that the judge and jury expressed themselves satisfied, and acquitted the girl.

Platner, in his *Quæstiones Medicinæ Forensis* (*De venia Ætatis*), gives a case in some respects so like this, that I cannot prevail

on myself to pass it by unnoticed. A girl, only fourteen years of age, the daughter of poor parents, who were obliged to send her out to service to procure a livelihood, became remarkable for her ill-temper and obstinacy. She was ill-grown and feeble for her age, and conceived a mortal hatred for the task-work imposed upon her. One evening, after much sullenness, she hastily finished her supper, and set fire to her master's barn. She took lighted coals from the kitchen fire, and put them under the straw; but never attempted to make her escape or to conceal herself during the confusion that ensued. When the conflagration was suppressed, without being at all questioned on the subject, she volunteered to assert her innocence. But when taken before the magistrate, she fully confessed her guilt, alleging, as her only excuse, the severity of the labour she daily endured: though how this was to be lightened by setting fire to the barn, she neither could tell, nor could the magistrate understand. No malice could be imputed to the girl: her disposition was generally benevolent, and even her master and mistress could not but give a good character of her in other respects. A plea of insanity was thought of, but it was deemed impossible to render it valid, since no other overt act, or word, indicative of deranged intellect, could be adduced. Her defence was then rested on the fact, that though in point of age, as legally determined, she was within the verge of responsibility, yet as her physical development was retarded, and in reality she was still a child in respect to her moral nature, she could not be justly arraigned for what she had done. The Leipsic faculty were consulted on the case, and all the circumstances fully investigated. The signs of puberty were wanting, and there appeared to be no indication of the commencement of the catamenia. The memory was not deficient, nor was there any want of connexion in the girl's ideas; but there was a manifest absence of that judgment and steadiness of attention, without which there can be no choice as to what is to be desired and what shunned, nor any understanding, or power of observing, laws either natural or civil. A report to this effect was drawn up, and it seems to have procured an acquittal.

In another case, also related by Platner, (*De excusatione Ætatis*), and which was almost identical with the preceding, a girl of fourteen, but of retarded growth for her age, was excused on that ground from the consequences of the crime of arson; but on a subsequent trial for a re-

petition of the offence, she was capitally condemned and punished.

Osseous system during puberty.—The bones undergo remarkable changes during this period. The coracoid process of the scapula, at *fifteen*, becomes united to that bone above the glenoid cavity, and several irregular osseous points may be observed at its summit. There is also an osseous point at the inferior angle of the scapula. Between *fifteen* and *sixteen*, the epiphysis of the olecranon forms a junction with the rest of the bone. At *sixteen*, the cartilage which binds round the os innominatum of the pelvis exhibits some bony deposits, and the epicondyle of the humerus ossifies. Between *sixteen* and *seventeen*, the five epiphyses of the *phalanges* of the toes are united to the bones; and at *seventeen* the same occurs with respect to the posterior epiphyses of the *phalanges* of the same parts. At *eighteen*, the epitrochlea and the three epiphyses of the superior extremity of the femur, become conjoined with the bone; the toes also present still further development in their bony structure. About *nineteen*, there is observed an osseous germ at the sternal extremity of the clavicle: the fourth coccygean vertebra is ossified; and there is union of the inferior extremity of the femur, and the two extremities of the humerus with the body of their respective bones. At *twenty* or *twenty-one*, the first piece of the sternum is usually found united with the other portions of that bone. The sphenoid also is observed to be in close union with the occipital.

The fifth molar teeth—the *dentes sapientiæ*—commonly appear from the eighteenth to the twenty-fifth year. But there is much diversity in this respect, for some persons have them not till very late in life. Dr. Hamilton mentions a man who died at eighty cutting his wisdom teeth. One thing, however, is pretty usual with respect to these teeth, that as they are commonly the last to appear, so they are generally the first to decay.

Youth or Juvenility.

Let us now direct our attention to that period of life—youth, juvenility, or adult age—in which the system reaches its zenith; when both mental and bodily vigour attain a degree of perfection which the subsequent ages at best only serve to concentrate.

Legal distinctions.—After the age of *twenty one*, and until that of *sixty*, males are liable to serve as jurors. In the church, no person is to be ordained deacon until he has attained the age of *twenty-three* complete; nor priest until he has completed *twenty-four*. That males and females, on attaining the age of

twenty one, are *sui juris*, at their own disposal, and in full possession of the rights and responsibilities of members of society, has already been mentioned.

Physical and moral indications.—Our best means of judging of the age of an individual at this period of life are far from being exact. Of the living we must form our estimate from the general appearance, and the expression of the features—making all allowance for labours undergone, climates visited, peculiar diet, trade or profession, &c. Beside this, Foderé thinks we have no good physical sign, save the stiffness of the beard; nor moral, except the superior steadiness and prudence exhibited in this period above that which went before. Of women it is perhaps more difficult still to form a correct opinion of the age, as at this period, owing to their peculiar destiny, they enjoy a remarkable immunity from those changes commonly attendant on the lapse of time. But in judging of the dead we may have recourse to the osseous system, which, as in the other ages, will present us with a few peculiarities that may assist us.

Osseous development.—About the *twenty-fifth* year the points which crown the transverse and spinous processes of the vertebræ become united; as, also, do the epiphysary points of the ribs. From *twenty five* to *thirty*, the first sacral vertebra forms a union with the rest. And this, perhaps, with the mere exception of the bony union which takes place between the ensiform cartilage and the sternum, and that between the coccyx and the sacrum (both which phenomena usually occur between the fortieth and fiftieth year), may be considered as the age in which the growth of the bones is complete.

As to the *teeth*, it has been sometimes thought that it might be possible, from a close observation of their wear and tear, to gather some clue to the exact age of the adult individual. But this method, so successfully pursued by veterinarians, and others conversant with the lower animals, cannot be applied to the human subject. The teeth vary very much in different individuals, and are of a very fragile and decaying nature in persons of weakly constitutions: all men, besides, do not employ their organs of mastication alike; some use them but little, *baking* their food with impunity; others employ their incisors where the molars are commonly used, and *vice versa*; others, again, owing to the unevenness of their jaws, one projecting beyond or beside the other, cannot use the corresponding parts of opposite teeth, and therefore wear them laterally; others, in fine, are in the habit of grinding their teeth in their sleep; so that,

on the whole, it must be evident that no certain characters can be detected in the condition of the teeth which can much serve the purpose of the medical jurist.

Proportions of the skeleton at different ages.
—Having noticed the successive changes that take place in the osseous system, from its commencement to its completion, we may here pause to take a survey of the proportions which the parts of the skeleton bear to each other at different ages. M. Sue, so long ago as the year 1755, made a series of interesting observations on this subject, and most of the continental

writers have adopted his conclusions. His method was to measure the subject from the crown of the head to the sole of the foot; he then measured the trunk, from the crown to the symphysis pubis. In taking the length of the upper extremities, he measured from the prominence of the acromion to the end of the middle finger; and in measuring the lower, he took from the symphysis pubis to the sole. The following are some of his chief results, communicated to the Royal Academy of Sciences :—

Age.	Length of body.			Trunk.			Upper extrem.			Lower extrem.		
	Ft.	In.	Lin.	Ft.	In.	Lin.	Ft.	In.	Lin.	Ft.	In.	Lin.
Six weeks	0	0	16	0	0	7	0	0	5	0	0	4
Three months.....	0	3	0	0	2	1	0	1	1	0	0	11
Six months.....	0	9	0	0	5	8	0	3	7	0	3	4
Seven ditto.....	1	0	0	0	6	5½	0	5	10	0	5	9
Eight ditto.....	1	2	9½	0	8	3½	0	6	8	0	6	6
Nine ditto	1	6	0	0	10	0	0	8	0	0	8	0
One year.....	1	10	6	1	1	6	0	9	0	0	9	0
Three years.....	2	9	0	1	7	0	1	2	0	1	2	0
Ten ditto	3	8	6	2	0	0	1	7	0	1	8	6
Fourteen ditto	4	7	0	2	4	0	2	0	6	2	3	0
Twenty to twenty-five ..	5	4	0	2	8	0	2	6	0	2	8	0

After this the proportions do not vary, except it be in consequence of old age giving a curve to the spine. It will be observed, therefore, that when the osseous system has attained its full magnitude, the skeleton is exactly halved at the symphysis pubis; and putting this in connexion with the fact mentioned in last lecture, that the middle point of the whole length is, at birth, at the navel, and that at the sixth month of gestation it coincides with the lower extremity of the sternum, we become acquainted with the peculiarity, which, when once known, is easily retained in the memory,—namely, that the middle point of the length, during the period of growth, from the embryo state to adult age, traverses from above the abdominal extremity of the sternum down to the symphysis pubis, where it stops.

But it must be recollected that this is the condition of the *normal* development of the bony structures. Where physical causes have operated to interfere with the growth, the results are strikingly different. The trade, or occupation, in which an individual may have been engaged during early life, may be an impediment. One instance of this kind may be found in the labour of the factories, as it used to be exacted of young per-

sons still growing. A remarkable example was mentioned in the evidence before the Parliamentary Committee, on the Factory question, in 1832. The witness, a medical man, showed how some of the operatives whom he had examined in the factories, must have lost, during their growth, a full foot of their entire stature,—and, as it would appear, through suppression of the growth of the lower limbs. He proved it in this way: it is known that when we extend our arms horizontally and laterally from the trunk, the distance between the tips of the fingers of each hand is equal to the whole length of the person. Now some of the factory workmen could with their extended arms reach over a space measuring six feet, while their stature did not exceed five. The deficiency he attributed to their standing constantly for fifteen hours or more in the day at work, during that period of life when the bony system is in a state of growth*. It is to be regretted that in this case the witness did not state the comparative lengths of the trunk and lower extremities. Still, however, the illustration is valuable, coming, as it did, from a quarter in which the researches of M. Sue appear to have been unknown.

* MEDICAL GAZETTE, vol. xi. p. 597.

An unhealthy or *diseased* condition of the bones in early life may also materially affect the proportionate lengths, as found on measuring the adult skeleton. Rickets has this effect in a remarkable manner. In a curious paper on this subject by Mr. Alexander Shaw (*MED. GAZ.* vol. xvi.), the author says, "that the rickety skeleton has a nearer resemblance, in its relative proportions, to the skeleton of the child, than to that of the adult." And it is worth observing, that in these cases it is generally the bones of the lower limbs that suffer. "The pelvis and bones of the lower extremity," says Mr. Shaw, "fall short to the extent of about one-third of their natural dimensions; while the skull, the spinal column, and the upper extremity, only suffer a loss amounting to about one-thirteenth of their natural size."

In persons who are very tall, or who exceed considerably the ordinary height, it will generally be found that the length of the lower extremities, measured after M. Sue's method, exceeds considerably that of the trunk. In fact, there is here a deformity the reverse of that resulting from rickets, or from premature exertion in a standing posture. Mr. Shaw tells us, that he took the measurements of a gentleman who stood six feet four and a half inches, and compared them with those of another gentleman whose height was five feet eight: the result was, that in the part of the body above the pelvis there was scarcely an inch of difference between the two individuals; while in the part

reaching from the spine of the ilium to the heel, there was a difference of no less than eight inches!

This will account for the unsatisfactory conclusions arrived at by those who have attempted to ascertain the human structure from detached parts of the system. In the case of animals, for obvious reasons—such as their comparative immunity from disease, their attitude not being erect, &c.—the dimension of any one bone may conduct us pretty correctly to those of the whole figure. But the statistical data gathered by Orfila and others with a view to arrive at the structure of man in a similar manner, afford no prospect of medico-legal utility. We find in the *Traité des Exhumations juridiques*, by Orfila and Lesueur, two tables—one giving the measurements of fifty-five recent subjects, including those of the femur, tibia, fibula, humerus, cubitus, and radius; the other stating the lengths of the same parts in twenty skeletons. But when we come to inquire what is the stature corresponding to a particular bone, we find that we may be left in doubt whether the person to whom it belonged was only five feet four, or five feet nine or ten in height!

M. Devergie shows the fallacy of the method by drawing up a table, of which this is a copy. He takes the tibia as the bone from which we may be desirous of drawing an inference, stating its length at 37 centimètres (14.54 in. Eng.), as he finds that to be set down as the length of the tibia in about 12 of the 51 subjects.

Tibia.	Femur.	Lower Ex- tremities.	Upper Ex- tremities.	Trunk.	Stature.
cents.	cents.	cents.	cents.	cents.	mètr. cents.
37	44	85	75	85	1 70
37	46	87	78	86	1 73
37	46	87	78	86	1 73
37	46	85	72	84	1 69
37	45	84	76	80	1 64
37	45	81	75	85	1 66
37	45	83	75	86	1 69
37	45	84	77	86	1 70
37	44	85	75	85	1 70
37	45	88	78	89	1 77

On inspection of the last column we perceive that the stature may be either 1 mètr. 64 cents. (5 feet 4½ inches English) or 1 mètr. 77 cents. (5 feet 9½ inches English) giving a difference of five inches between the extremes. Yet M. Orfila, contemplating his tables with some complacency, says that he is convinced of the possibility in the greater number of instances, of

arriving at the truth, if we avail ourselves of his results, especially if we take the *femur* or the *humerus* as our standard. On consulting his tables, however, with reference to these bones, thinking it possible that M. Devergie's instance of the tibia might be partial, we find the facts to stand thus:—

Femur.	Stature.	Humerus.	Stature.
45	1·68	32	1·73
45	1·69	32	1·68
45	1·70	32	1·73
45	1·64	32	1·68
45	1·67	32	1·70
45	1·66	32	1·69
45	1·69	32	1·70
45	1·70	32	1·66
45	1·68	32	1·68
45	1·70	32	1·69
45	1·77	32	1·80
45	1·75	32	1·64

So that we should be still more unfortunate with these parts than with the tibia, being left in doubt respecting the stature corresponding to the humerus to the extent of above six and a half inches, and with regard to the femur, five.

Manhood.

Physical appearances.—Although the period of manhood is not characterized by any of those well-marked and positive signs which it would be peculiarly the province of the medical jurist to determine, still there are appearances sufficiently indicative of the time of life. This is the

period when, if ever, the system attains its perennity: it is mature, and preserves its high condition for several years. Sometimes the person grows more stout, and of fuller habit. The features are more deeply set, and the forehead bears traces of care. Women, especially those who are mothers, exhibit much the same permanence of general appearance, and undergo little or no change until the cessation of child bearing. Upon the occurrence of this epoch, which commonly dates about the forty-fifth or fiftieth year in this country, it frequently happens that the mental powers become developed to a high degree of perfection. Of the moral qualities, however, of either sex, it is unnecessary for me to speak, as they are too various and diversified for the purposes of the medical jurist.

Height and proportion in mature manhood.—The first portion of this period of life—from the age of thirty-five to forty—may be considered as that in which the body is in its full vigour and prime proportion. Here is a table of the heights of the men of a Scotch militia regiment, with a statement of the average circumference of the chest corresponding to each grade of stature.

Strength.	Stature.	Number of men.	Mean circumference of Chest.
	ft. in. ft. in.		inch.
686	5 4 and 5 5	79	38·7
	5 6 .. 5 7	221	39·2
	5 8 .. 5 9	245	40·5
	5 10 .. 5 11	107	41·1
	6 0 .. 6 1	34	42·4

From this statement we may draw the curious inference, that for every two inches of height the measurement round the chest increases one inch. If the men, who were six feet one inch high, had been as large in proportion to their height, as the men who were five feet five, they would have measured 43·4 inches round the chest, instead of 42·4. Mr. Marshall, to whom we are indebted for this observation, gives several others of a similar kind in his book on the Enlisting, Discharging, and Pensioning of Soldiers. I may add to the statement in the table, relative to the average thickness round the chest, that the extremes of the measurement of all the Scotch regiments of local militia were as follows:—Three men were only thirty-three inches, and nineteen thirty-four; three were forty-seven, and one man forty-eight, inches round the chest.

Senescence.

Physical characters.—Our means of judg-

ing the age in this period of life are far from exact. Some, who are actually between fifty and sixty, are as hale and vigorous, and have as few marks of the imprint of time upon them, as many who are not yet forty; while, on the other hand, as Byron has said,—

“ There is an order
Of mortals on the earth, who do become
Old in their youth, and die ere middle age,
Without the violence of warlike death;
Some perishing of pleasure—some of study—
Some worn with toil—some of mere weariness—
Some of disease—and some inanity—
And some of withered, or of broken hearts.”

The skin and lineaments of the visage betray manifest signs of advancing age. The person generally becomes meagre, and loses its erect aspect: not unfrequently, however, a high degree of *embonpoint*, or rather obesity, prevails. A diminution of vigour and activity is more or less observable. As to greyness of the hair, baldness, wrinkles, sunken eyes, and decayed teeth and jaws—observations

founded on such characteristics as these, unless several of them be taken in combination, can scarcely avail for medico-legal purposes.

Decrepitude.

The period of decrepitude—"last scene of all, that ends this strange eventful history—second childishness, and mere oblivion,—sans teeth, sans eyes, sans taste, sans everything,"—that age which is usually described as commencing about the eighty-first or eighty-fourth year,—I cannot help observing that it appears to be considerably antedated. We can scarcely call to mind the advanced ages of Goethe, Bentham, and some others, who have recently died, possessing to the last the highest vigour of intellect; nor can we reflect on the many distinguished persons still living, who have passed far beyond the "threescore and ten," and even the "fourscore," allotted to the more strong among the sons of men, without being impressed with the idea that there must be some real improvement in the habits of life in latter times, which preserves the stamina, and keeps the "*mens sana in corpore sano*," up to an age described by our predecessors as the mere wreck of human nature.

Physical characters.—The state of the osseous system is at this time characteristic. The bones of the head are very solidly united, but they are thinner than in earlier life. The lower jaw has the appearance of great wear and tear, the teeth have in general all disappeared, and the alveolar processes are wanting. But, with all their solidity, the bones are very deficient in gelatinous or animal matter; whence they are more friable and dry. The spinal column is usually more or less curved. The larynx is completely ossified, and so are the cartilages of the ribs. These signs, however, of very advanced age, are applicable to a period embracing many years of life—the interval is large in which they are observable: so that we are obliged to gather more exact information, if it is to be had, from moral or collateral circumstances.

I shall here close my remarks on age. A multitude of other considerations, which have sometimes been looked upon as connected with the subject, might easily have been introduced, and probably would have served both to amuse and instruct you: but I have thought it right to omit all such as do not immediately belong to our province; and most of those to which I allude have certainly more relation to natural history, or to medical police, than to Forensic medicine.

MEDICAL PROBLEMS.

By D. GRIFFIN, M.D.

HOW ARE WE TO DISTINGUISH SYMPTOMATIC FROM IDIOPATHIC INTERMITTENT?

IN the month of March some years since, when intermittent fever was very prevalent in the country, James M'Namara, a healthy young man, 21 years of age, was attacked with fits of shivering, accompanied by pain in the left side of his head; these fits were succeeded by heat of skin and quickness of pulse, of some hours' continuance, and ended in profuse perspirations. At first the paroxysms came on rather irregularly, but afterwards they occurred on every second day, for the most part at the same hour, and with increasing severity. When I was called to see him, he had been suffering in this way about eight days; the paroxysm had just then gone off, and left him in a low, weak state, with slow feeble pulse, and some headache, which was worst at the left side, but was no where very severe. Tongue whitish; face pale, and covered with a clammy sweat; the bowels had been tolerably free all through, and he had scarce any thirst except during the fit. I ordered him a drachm of the compound powder of jalap immediately, and a tea-spoonful of Peruvian bark three times a day. On the 25th the fits of shivering were repeated once or twice; but the bark being continued, they went off, and did not return for some days. On their recurrence I was again called to see him; the fits of shivering were much more irregular than before. For the last four or five days he had pain in the vertex, and that which he had in the left side of the head was very severe about the left mastoid process and ear. He could get no sleep, and suffered much during the last two or three nights; but there was no tendency to delirium. His pulse was 95, and hard; his tongue whitish; and there was very little thirst. His face looked pale, was covered with a clammy sweat, and had an expression of great anxiety. There was a tumor over the mastoid process at the left side, which was soft, puffy, and fluctuating, on opening which, a quantity of extremely

foetid brownish pus sprang out with great violence, and much relief. The bone was carious to the extent of about a shilling.

As this patient lived at a considerable distance from me, I found it impossible to see him every day, or, indeed, at all as often as might be wished. After the opening of the tumor he got a purgative, and had relief from the paroxysms for a day or two; but they came on again with more than usual severity, and occurred daily instead of every alternate day; they were also much more regular than before, the cold fit commencing exactly at noon, lasting about half an hour, preceded by a hot stage of somewhat longer duration, and terminating in profuse perspiration. I saw him in one of the intermissions: the pain in the head was trifling, and there was no thirst nor heat of skin; the face was pale, the tongue slightly white, the bowels free, and the pulse calm, at about 75.

As these paroxysms bore a perfect resemblance to regular intermittent fever, of which there had been for some months a good deal in the country—as the intermissions were so perfect, the pain so trifling, and above all, as it had before yielded to the influence of bark, I was not at all convinced that the symptoms depended upon suppuration within the head. I had never seen the shiverings attendant on internal suppuration so perfectly periodical; and there was no improbability in the coexistence of such an abscess as I described with idiopathic ague. I determined, therefore, on trying the bark again: the subsequent history of the case proved, that though it once more gave very unaccountable relief, it was a remedy entirely inapplicable, and convinced me of the great necessity there is for minute inquiry in cases so very insidious as these are.

The discharge from the wound, which had been a good deal for some days, began to diminish considerably; the fits also disappeared, the intermission lasting from the 3d to the 6th of April. He was then attacked with pain in the head, very severe in the vertex and mastoid process, and attended with violent shivering fits frequently in the day; great thirst, heat of skin, vomiting, and delirium; no drink remained on his stomach. His face was flushed, his pulse hard, at 110, and he was very restless. The pupils of the eyes were not dilated, but he lost his sight in the

night for about ten minutes. The case was at this period evidently hopeless, unless something further was done. I had brought no instruments for trephining with me, and the place was many miles from my residence; but at all events the necessity for it did not seem very apparent, as the matter was flowing with sufficient freedom from the opening near the mastoid process. The only other obvious indication was to diminish the inflammatory action; and with this view I took twenty-six or twenty-eight ounces of blood from the arm: the vomiting ceased soon afterwards, and he seemed somewhat relieved. It was then late at night; and on my return next morning, I found he had expired about three o'clock. There was no examination of the body: an application for that purpose is seldom successful with people of this class in the country, and was not in this instance made, as I knew it would be useless.

Some time afterwards a boy, 10 years of age, was brought to me by his mother. He appeared very ill, and the resemblance the attack bore to that just related was very remarkable. She said he was seized at first with pain in the head, accompanied by frequent irregular fits of shivering. In about a week from their commencement these assumed a more regular character, occurring precisely every second day, and followed by a hot and sweating stage, as in the case of intermittent fever. He had been affected in this way about a fortnight: when I saw him his pulse was 95, and weak, his tongue whitish, his face pale, anxious, and covered with a cold perspiration. The skin was cool, but he had much thirst, and was very feeble; his bowels were rather confined, and he had lost his appetite. Again looking on it as a case of ague, I ordered him half a drachm of pulv. jalap. comp., and some pills of sulphate of quinine, three times a day.

The mother returned to me in four or five days to say that he was much better, the fits had gone off, and his strength was improving; the thirst and debility were much less, and he was altogether so much better, that she thought he only wanted something to restore his strength. A repetition of the medicine was accordingly ordered. In about a week from this time she came again, to inform me that he had got a return of shivering fits; that they

now came on every day, sometimes two or three times; that he had been twice growing gradually worse since their recurrence, and was at last very bad; she said that he had great oppression, with delirium, much restlessness, and excessive thirst; that he had been delirious the whole of the previous evening, and all night, and that he had refused drink since morning. The oppression was hourly increasing, but he was still able to speak when she left him; she also mentioned that he had complained much more than usual of his head the last four or five days, and that there was a tumor behind his left ear; she now also, for the first time, told me that he had been long subject to an occasional suppuration in his left ear. I went home with her to see him, but he had just expired as I entered the house. On looking at the body it appeared to be much wasted. The tumor was situated exactly above the mastoid process, as in the other case, and was soft and fluctuating. I was anxious to examine the head, but knew it would be quite useless to make application for leave to do so. There cannot, however, I think, be a doubt that there was matter under the skull, and that it had made its way through, as in the former case.

I shall give one instance more of this formidable affection, which, though not attended by ague, nor by any external appearance of abscess, proved on a post-mortem examination to have been exactly of the same nature.

Mary Cronon, a married woman, aged 24 years, applied at the Dispensary, complaining of a pain in her ear. The case was looked upon as one of common cold, and did not attract any particular attention at the time. The sunk and distressed expression of her countenance alone a little surprised me; but I attributed it to her having been deprived of sleep for two or three nights. Some days after her husband called on me, to say that she had no relief from the violent pain, but was much worse, and unable to leave her bed. On calling at the house I found her in a most deplorable state. The pain had extended from the ear to the back of the head; the countenance was heavy and stupid; the pupils greatly dilated; the skin warm, and covered with clammy perspirations; the tongue white; the pulse small and very feeble, at 110; and there were constant retching and distressing thirst. On pressing the right hypo-

chondrium she complained of pain. I had now no doubt of the nature of the case, but it appeared to have passed the period at which bleeding could be of any avail. The head was shaved; cold lotions were applied to the fore part, and the whole occiput was blistered; active purgatives were also ordered. She grew more listless and heavy on the following day, and was in some degree deaf, but was sensible; and when spoken to in a loud voice, answered questions distinctly. The skin was cold, and covered with clammy moisture; she complained of the intensity of the pain in the head, and, for the first time, in the back of the neck; she took drink well, but the retching continued at intervals. In the evening she roused herself up, apparently excited by a strong presentiment of her approaching dissolution; called her friends about her; said she felt she could never recover, and in a very affecting manner recommended her little child to the care of her mother and husband. As if she had then accomplished all that she could have any concern for in life, she sunk back into the same listless state as before, equally indifferent to the cries of her infant or the complaints of her family; she moved on the pillow with caution, complaining dreadfully of the back of the neck, and now and then sawing the air to and fro with her hands: she suffered intensely whenever her head was raised to give her drink, and at night had involuntary evacuations. I saw her, for the last time alive, on the following morning; she was lying on her side, frothing at the mouth, with a cold, clammy skin, ghastly expression of countenance, the lips pallid, and the eyes filmy; her pulse still distinct, at 95; she spoke rationally, and complained of the pain in the neck when questioned. Anxious to ascertain whether she could swallow, I had her raised to give her some drink, to which, however, she strenuously objected, exclaiming, "'twill choke me, 'twill choke me!" She was, however, induced to make the attempt, and had such difficulty that it was near suffocating her; her head was laid back on the pillow, and she expired in about half an hour.

The examination was made three days after death. There was unusual difficulty in detaching the cranium, from the close adhesion of the dura mater; the pia mater was not particularly vascular; there were about two ounces and

a half of water in the lateral ventricles; the choroid plexus and velum interpositum were unusually pale; the pineal gland was very soft, and contained none of those gritty particles commonly met with. On raising the tentorium, the cerebellum was found covered by a layer of thick pus, which extended over the upper surface as far forward as the cavernous sinus, into which it had passed through the aperture in the dura mater which transmits the fifth pair of nerves; it had also insinuated itself into the meatus auditorius internus. The pia mater and arachnoid membrane investing the cerebellum were highly vascular, and spots of extravasated blood were observable; this was also the case at the base of the cerebellum and the commencement of the medulla oblongata, though no matter was found there. The quantity of matter on the whole amounted to something more than an ounce. The substance of the brain and cerebellum differed little from the natural state; no other morbid appearances were found except in the liver, which was considerably puffed out below the ribs, with a round thickened margin; it was of a bluish colour, and its substance was of a soft spongy texture. She had never complained of her side until after she was attacked with pain in the ear.

• The cases of this description recorded in medical writings are very numerous, and many of them have been found to resemble intermittent fever so strongly, that their real nature was entirely unsuspected until the progress of the disorder disclosed it, though generally at a period too late for relief; it is, therefore, a matter of the utmost consequence to be able to distinguish them in the early stage of their attack, the only time we can hope to find our efforts available. Unfortunately, however, in diseases such as these, which are not always very rapid in their progress nor constantly acute in their course, it seldom happens that we are consulted early enough to have it in our power to prevent the occurrence of suppuration, and as the only rational practice, if the symptoms indicate that it has occurred, would be to trephine as soon as we can ascertain the seat of the matter, it would be a vast advantage to be able to tell when this has happened. We are much in want of facts on this subject, and it would require considerable experience in cases of this kind *to be able to determine what connexion the rigors, or in-*

terminating paroxysms, have with the actual existence of suppuration. In the present state of our knowledge, however, their occurrence is the first circumstance that usually leads us to suspect that it has occurred, but we see that in their close imitation of a much less serious malady, they are, in some instances, likely to deceive us. The pain in the head in itself, except when fixed to one spot, cannot give any particular indication, as in common colds, in disordered stomach, and in the paroxysms of all intermittents, it is very severe. It is probable that more may be gathered from observing the changes of countenance closely, than from any other symptom whatsoever. It will, I believe, almost always be found, that even where the intermission is complete in other respects, the countenance bears evident signs that the patient is labouring under a serious and dangerous disease. In the advance of the disorder it becomes still more indicative of the deadly mischief which is going on within; the face and forehead are covered with a cold and clammy sweat; the features are sunk and ghastly, and there is on them an expression of extreme distress and suffering. These signs are not altogether peculiar to the cases before us, but, I think, may be observed in all instances, whether chronic or acute, in which matter is forming beneath the skull. I should, perhaps, except some of those in which this state of things has arisen from external injury, as I think I have seen some in which this expression was not strongly marked, or was altogether wanting. It seems probable that in the instances given the inflammation was neither violent nor extensive in its first attack, but that it was confined to a small spot which suppurated after the inflammation had lasted some days, and, by pouring out matter, separated the dura mater in its immediate neighbourhood; this in its turn becoming inflamed, added to the quantity of confined matter and to the severity of the symptoms, and, at length, from the continuance of this process, and the impossibility of the matter finding an outlet, the inflammation became very extensive and intense, adding every hour to the urgency of the symptoms and the certainty of the event. This view of the circumstances seems to be supported by the fact well known to medical men, that diseases so serious and dangerous as these, very

often have their origin in the simple and apparently trifling fact of a child having a purulent ear, and leads us to perceive, in the strongest manner, the great difference there is with regard to the event, between the brain, when any part of it or its membranes is in a state of suppuration, and other parts of the body. The bony covering which is placed round it, to protect it from injury, is, when suppuration occurs in the brain, the main cause of destruction. In any other organ of the body, even in many of those which are concerned in the most important vital processes, large abscesses frequently are formed, and many of the persons affected with them escape, and even enjoy perfect health afterwards; but in the brain, the smallest abscess occurring, even so small a one as sometimes in slight cases of whitlow separates the nail from the finger, is obviously attended with the utmost danger to life, and must necessarily prove fatal except in the small number of those cases which come within the reach of surgical aid, and the still smaller number in which the matter is absorbed.

Hence it should be a constant rule of practice in the treatment of diseases of the brain, *never to admit even a hazard of inflammation, however slight or circumscribed, terminating by suppuration.* In other organs, if it occur, there is still some hope left; in the brain there is virtually none*.

[To be continued.]

ON LITHOTRIPSY,

AS PRACTISED BY THE LATE PHILIP FERNANDEZ, ESQ.

(From a Correspondent.)

IN recording the death of this estimable young surgeon, which occurred on the 18th of September, 1836, we take the opportunity of laying before the medical public an account of an improvement which he had effected in the practice of lithotomy.

The attention of Mr. Fernandez had been directed to lithotomy by one of those apparently casual circumstances which so often form an æra in life. An operation requiring much self-possession and very careful dissection, which he had performed with great dexterity, having been mentioned to Sir Benjamin Brodie, the friend and ready patron of

every pupil of rising merit, he offered to present him with a crushing instrument, should he be inclined to practise lithotomy. The offer was accepted, and Mr. Fernandez, with that unwearied zeal which formed so bright a part of his professional as well as private character, took every opportunity which the dead-house of a considerable parish infirmary afforded of practising the operation.

By repeated experiments he worked out the principle which enabled him to seize the smallest portion of stone in the bladder of the living body, twenty-eight times out of thirty, in the shortest space of time possible.

In his first operation, he seized and crushed the stone in 2½ minutes. He lost time, indeed, by following the recommendation of a friend, and endeavouring to grasp the stone between the blades of his instrument; for he found that at each attempt it escaped. He came, therefore, to the conclusion, that, in this method, success would depend upon accident; nay, more, that the attempt to grasp the stone pushed it away from the operator.

The failure of what would seem, at first sight, to have been the obvious and natural method of seizing the calculus, confirmed the truth of the theory of the operation, which frequent meditation and practice on the dead body had led him to entertain, and at which he had arrived by what deserves to be called a surgical analysis; whence he had deduced the simple and beautiful principle on which his future success depended.

He saw that when the bladder was injected the surface would no longer be rugous, but smooth, and that the stone would consequently be sure to roll to the lowest spot. He made it a rule in his operations, therefore, to come exceedingly close to the stone (whether before or behind, mattered not) without touching it; and then, having first opened his instrument, he gently pressed the part. The spot touched being thus made the lowest part of the bladder, the stone uniformly rolled into the instrument, and he had nothing to do but to close it and crush the calculus.

Twenty-eight times out of thirty did this method succeed, as we have already stated, and the stone was seized in half a minute, to the no small surprise of the by-standers; and thus, in our opinion, has Mr. Fernandez removed the grand difficulty of this operation.

* Dublin Journal of Medical Science.

It should, however, be remembered, that an instrument powerful enough to crush a mulberry calculus is still a desideratum in surgery.

Fortunate, indeed, it is for the world, when an operator can thus explain the grounds of his success, so that those results which at first seemed the exclusive reward of individual tact, may become the heritage of mankind.

Nor does this hope that lithotritry has now been deprived of its chief difficulty, rest solely on the probability of the theory and the success of its promulgator; for the same effects have followed in other hands.

By this method, Mr. Robert Bloxam, of Ryde, cleared the bladder of a stone in two sittings, with the same facility as Mr. Fernandez; and another operation, left unfinished by the deceased, was easily completed by Mr. H. W. Rumsey, of Chesham.

Thus, then, were these two gentlemen enabled to lithotritize with all the skill of adepts, without any previous opportunities of practice, simply by following the instructions of the lamented subject of this notice.

May we not, then, claim for Mr. Fernandez, too early snatched away from the affections of his friends, a portion of that praise which is awarded to those who, by adding to the stores of surgical knowledge, have diminished the sufferings of mankind?

His second operation was rendered more complicated by the extreme smallness of the orifice of the urethra, which required division, the intervention of spasm and hæmorrhage; yet, even with these difficulties to contend against, the first sitting was completed in five minutes.

Let us now detail a few other points relating to this operation, which were the subjects of his investigation.

1st. Concerning sounding. Mr. Fernandez conceived that it was possible to draw an imaginary line from some given point, varying with the position of the patient, so as to intersect the fundus of the bladder, and consequently lead to the stone itself. By availing himself of this, he became so dexterous that it has happened in a few instances, where sounding was really difficult, that he instantly succeeded in striking the stone. Guided by this imaginary line, he found on one occasion, in his early practice, the stone lodging in the curvature of the instrument.

He explained this circumstance in accordance with the theory which we have previously given, by supposing that by his having pressed a little in front of the stone, he had lowered that spot sufficiently to cause it to roll into the hollow of the sound.

He thought, too, that in cases where the presence of stone was suspected, the surgeon might do better than striking the parietes of the bladder at random: he preferred sweeping its cavity transversely, and forward, and backward; and this he was in the habit of doing, whether he used a flexible or stiff instrument.

When this method had failed, he was too cautious to feel perfectly satisfied of the non-existence of a calculus, if the symptoms were prominent, till he had placed the patient on a lithotritic bed and sounded again, in the injected bladder. He thought that if a calculus existed, it must then necessarily be detected. As the most eminent surgeons have sometimes overlooked the existence of a stone, this hint is submitted to their consideration.

It was the intention of Mr. Fernandez to have injected bladders of various sizes and shapes—to have made casts from them, and to have embellished his projected work on Lithotritry with drawings from these casts.

The utility of such delineations to the young operator cannot be doubted, as they would have shown what position the stone is likely to take up, according to the irregularity of the cavity in which it is lodged.

Whether the deceased's method of sounding may turn out so satisfactory to others as it was to himself, and the actual cause of his dexterity, or whether the more perfect method of sounding in an injected bladder, in suspected cases of stone, as he recommended, may render the decision of the question of its existence more perfect, remains to be confirmed by others. His method of lithotritizing stands on an immovable basis; and the adaptation of the simple truth of a stone's necessarily falling, in an injected bladder, to the fundus, to the important purpose of seizing it with facility in the manner described, must be considered as the effort of a mind of the same quality as that which forms the distinguishing feature of our greatest discoverers.

MEDICAL EVIDENCE
IN A
RECENT CASE OF SUSPECTED
INFANTICIDE.

LETTER FROM MR. PORTER.

—
To the Editor of the Medical Gazette.

SIR,

I FEEL highly obliged by your courtesy in calling my attention to a report which appeared in the *Times* newspaper of the 12th instant, and which professes to give a detail of the evidence taken at a coroner's inquest, held at Bishopsgate Workhouse on the 11th instant. As I do not generally read the *Times*, I was not aware of the insertion, and, in all probability, would never have been made acquainted with it, had you not drawn my attention to it. That it is a correct report, I think no liberal person would for a moment suppose;—what with omitting words necessary to the proper reading of a sentence, and substituting others, the evidence is, in many parts, any thing but what it ought to have been; and, to convince yourself and your readers to what extent a report of this kind may be varied by the reporter, I beg to recommend a perusal of a report which appeared in the *Morning Chronicle* of the same date.

I feel the full force of your observations respecting the propriety of medical practitioners taking care that the opinions attributed to them in the newspapers be correctly stated; but, sir, with due deference to your opinion, I fancy this, in most instances, would prove no easy matter, and I think that those gentlemen who are in the habit of being called upon to attend coroners' inquests will bear me out in this assertion. Evidence is put into their mouths which they do not always utter; questions are so shaped with regard to probabilities, and are often so edged by collateral circumstances, that whilst you are directing your attention and framing your answer to meet one part, a reporter places what you have said to a different account. With respect to the report in question, I could have wished, since the case must go before another tribunal, that it had not been necessary for me to go into it at this time; but as it has been allowed to go forth in an imperfect and very incorrect state, I think I am justified in endeavouring to counteract its

effects, and which can only be done by giving a just one.

To the best of my recollection, my evidence was as follows:—I yesterday, between one and two o'clock, received an order to attend F. Douglass, at 2, Sweet-Apple Court. I found her in bed, and, upon examination, I ascertained that she had been recently delivered. I inquired what had become of the child: she said it had been put away. I then desired her to be cautious, and asked if it was born alive. She said it was. I inquired how she knew; when she said she heard it cry. (It may be necessary to state that this took place before the child had been found). I subsequently examined the body, which presented the appearance of a well-formed child at the full period of pregnancy; the head well covered with hair, the nails perfect, and the chest well expanded. The lungs gave the usual evidence of having been distended, which must have been with atmospheric air, as the child had recently been born, and could not have been the case unless the child had breathed. They (the lungs) were crepitous, and, on being cut into, air, mixed with frothy fluid, issued from the cells. There were no external appearances to account for death.

The following part of the deposition was in the shape of answers to questions put by the coroner, or jurors:—

It is *barely possible* it might have died from natural causes before being put into the cesspool. It might have died from not having proper assistance, if the position in which it was born was unfavourable. I cannot say that death *was* the effect of natural causes; there were no external appearances except slight lividity of the lips. Would not say that it had died by violence, nor that it had not.

Two sons of Hall, aged 15 and 13, were then called, who deposed to the following effect:—They lived with their father, and slept in the same room on Monday night; they were awakened during the night by the illness of the young woman Douglass, who complained of pain in the stomach. There was no urinary utensil in the room; but there was a pail which is kept by their father, who is a shoemaker, and used by him in his trade; it generally contains water. The young woman got up and sat on this pail for some time, and was then helped into bed by their father,

who afterwards lighted a candle and gave it to the younger boy to light him down stairs, whilst he carried the pail, which was covered over, and emptied it into the cess-pool.

On hearing the above evidence, I then stated that in all probability the child was born whilst the woman was sitting on the pail; that she, not being aware of the actual state of the labour, probably mistook the pressure caused by the child for an inclination to relieve her bowels, and desired to be placed upon the pail; in which case, as soon as the child's head was protruded it would cry. In a few seconds another pain would expel the shoulders, and then the whole body; on which it would fall into the pail. Now if the supposition be correct that the pail contained water, it would immediately be drowned; and even if there were only the discharges incidental to labour, they might, at the bottom of a narrow vessel, be sufficient to suffocate the child, aided by a favourable position, with the face downwards. My opinion is, that the child died soon after birth, from suffocation; but whether that was accidental or otherwise, I cannot say.

For reasons before stated I shall abstain from making any comment on the above; but it may not be improper to observe, that in cases of this kind, when public excitement generally runs high, it behoves the medical practitioner to be very guarded in his evidence; and if there be any room for doubt, surely the accused ought to have the benefit of it.

I have the honour to be, sir,

Your very obedient servant,
THOMAS PORTER.

145, Bishopsgate-street,
Oct. 16th, 1836.

THE LATE MADAME MALIBRAN.

To the Editor of the Medical Gazette.

SIR,

PERMIT me to make a few observations, suggested by your remarks on the death of Madame Malibran. By so doing, I am far from wishing to add to the irritation which this catastrophe has occasioned,—of which, be it said, *en passant*, I have had personal proof.

From having formerly attended upon that unfortunate lady, and from the

similarity of the first syllable of my name, I have been mistaken for her late medical attendant, and have been exceedingly annoyed in consequence, to the great amusement of my professional friends, but little to my own satisfaction. Neither have I any intention of casting imputations on Madame Malibran's medical advisers. Her Manchester physicians are men of such well-known talent, that were I myself in danger, I should feel much reassured in seeing them at my bed-side. As to her homœopathic physician, I think that if a man practises openly a system fully explained to the public, and himself believes in his own creed, however absurd it may appear to us, he is conscientiously exonerated from its consequences*. To you, sir, who so well fulfil the office your epigraph sets forth — “*Dignitatem Artis Medicæ tueri*” — it belongs to overturn this new ephemera; a private individual, without the privilege of using the emphatic “we” of criticism, might be suspected of personal motives, if he attacked the homœopaths.

As far as I can judge by the reports of the case which have reached London, and to which I apply the intimate knowledge I possess of Madame Malibran's constitution, I think her death to be in a great measure due to the depleting system which it was very natural her first adviser should have adopted, not knowing the peculiarity of her nervous system, and for which they had not opportunity of compensating afterwards. A few details will prove this. Dramatic genius arises in a great measure from deep feeling; and this great tragic actress, for such she was above all, having, in the pursuit of her vocation, accompanied by great private sorrows, over-excited her nervous system, was subject to fits of hysteria akin to epilepsy, and to attacks of catalepsy, such as I have never seen elsewhere, and hope never to see again. For example; having been one day informed (falsely as it proved) that her brother was killed at Algiers, her whole frame became immoveable, and as suddenly as if she had been converted into a statue by the wand

* We are not aware that M. Belluomini has fully explained the practice he adopted: we know of no intimation of his treatment more specific, than that he “administered to the patient those remedies which he thought desirable.”—*ED. GAZ.*

of an enchanter. She remained standing for two hours, neither hearing nor seeing any external object. Waking from this trance when her attendants were off their guard, she unconsciously precipitated herself down a flight of stone stairs, cutting herself severely in her fall. Being taken up, she remained inanimate and motionless, until, in the middle of the night, she was seized by an automatic movement, when she began to roll over and over from right to left; such a motion as Magendie, if I remember right, describes as taking place when the cerebellum had been pierced in a certain direction. Now, sir, for this malady, which I called my lamented friend, the late Dr. Maton, to witness, from experience of her constitution, no depleting remedy was applied, except a few leeches, in spite of the violent blow on the head. A day afterwards Madame Malibran insisted upon fulfilling her duties at the King's Theatre—was lifted into her carriage, not being able to stand—was taken out in the same manner—was dressed, while *sitting*, for her part in the *Semiramide*; and when the moment came that she was to appear, to the unutterable astonishment of her friends she rushed on the stage, and drew down thunders of applause by her unrivalled acting and singing. Every time she came off the stage she retched violently, till the blood came; and soon after the performance was over, relapsed into her insensibility. On other occasions, when other persons would have required bleeding, she recovered without it; and, on all occasions of illness, her frame required artificial support to a most unusual extent.

The last time I was called to her (the 23d April, 1833), it was for a severe sore-throat. I ordered some leeches to be applied in the evening. Being obliged to go out of town, I did not call again in the evening, as I had promised to do, before the application of the leeches. In my absence, a homœopathic physician was called, and attended her ever after. She then wrote to me to say that she had recovered without the application of the leeches, and, whenever I happened to see her, she laughed at my sanguinary system of *allopathy*, whilst I treated *homœopathy*, which had taken so ample a possession of her fancy, with similar irreverence.

I think, sir, these observations may

be useful in practice, and will illustrate how cautious we must be in treating patients, in the vocation of our lamented cantatrice, by depletion, when we are not aware of the peculiarities of their nervous system. There may, however, have been reasons arising from the peculiar situation of Madame Malibran, when at Manchester, fully authorizing the means adopted by her first able medical attendants.—I remain, sir,

Your obedient servant,

HENRY BELINAYE.

DISLOCATION OF THE ELBOW-JOINT.

To the Editor of the Medical Gazette.

SIR,

HAVING read in a late number of your excellent journal some very interesting cases of injuries to the elbow-joint, by Mr. Collier, I am reminded of an uncommon accident, to which I was called about twelve months since, in the person of a young lady, who was thrown from a gig, in consequence of the horse falling, and was precipitated with great violence to the ground.

On my arrival, about two hours after the accident, my attention was directed to the left elbow, which received its injury by the carriage during the fall, and, I have reason to believe, by the weight of the body falling upon the hand. There was total inability of the limb, which was slightly bent, and pronated, but an attempt at flexion, or extension, produced great agony. The joint was much swollen and deformed, but after some little time I discovered that the head of the radius was partially dislocated forwards; and on grasping the condyles of the humerus, and partially extending the forearm, I perceived also a decided crepitus at the internal condyle, which proved to be an oblique fracture of that bone.

The reduction was accomplished by fixing the humerus steadily, and making extension from the wrist, by which means the radius was brought into its proper situation; at the same time due compression was made at the fractured condyle. I immediately applied a bandage around the arm, bent the limb at a right angle, placed on a long splint,

had recourse to leeches, saturnine lotions, and the antiphlogistic treatment, and at the expiration of one month I commenced passive motion.

I have the satisfaction of adding, that although the elbow remains *partially* ankylosed, it is sufficiently useful for the common purposes of life.

Should you deem the above case worthy of publication, it is at your service, and I remain, sir,

Your obedient servant,
S. W. KIDGELL.

MEDICAL GAZETTE.

Saturday, October 22, 1836.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas modo veniendi in
publicum est, dicendi periculum non recuso."
CICERO.

FRESH ILLUSTRATION OF THE NEW POOR-LAW SYSTEM.

THE Poor-Law potentates have made an example of one of their officers: they have cashiered him publicly — *pour encourager les autres*.

But what a farce is this that they have attempted to play! In the sight of an offended community, well acquainted by this time with the thorough inhumanity which clings to their proceedings, they have had recourse to the most shallow trickery: with their character for narrow-souled tyranny branded on their front, they have ventured to try a delusion on the public—to create, if possible, a belief that they are actuated sometimes, if not by clemency, at least by stern justice, in the discharge of their duties. A poor wretch loses her life through the criminal inefficiency of the system adopted by the functionaries of the *amended* Poor-Law: public indignation is anticipated: they fasten on one of their degraded officials—unfortunately a member of our profession: they exercise their inquisitorial powers

over him: make him their scape-goat, and fancy they have thereby exculpated themselves from every imputation. The thing is too gross.

We protest that we are wholly free from any partial feeling in this matter. We have no sympathy whatever with the medical man who has been victimized for the expected benefit of his employers. He was probably a *contractor* for pauper medical attendance, and undertook to supply his medicine and advice at the lowest possible rate; otherwise we are satisfied he would not have obtained the appointment. At all events, in accepting the terms of the guardians, he undertook duties and an amount of responsibility which a conscientious practitioner would have shrunk from. He has forfeited, moreover, our good opinion, in submitting to treatment derogatory to the respectability of the profession; and has lowered himself in our estimation, by the pitiful concessions and mean promises which he tendered, of being no more guilty of such high crimes and misdemeanors, if their honours would but let him off this once. Yet the injustice of the case is too manifest to be obscured by the demerits of the sufferer.

The circumstances have appeared in the newspapers: they may, however, have escaped the notice of some of our readers, and it may be as well to state them briefly.

On Wednesday, the 3d of August last, at three o'clock in the afternoon, application was made to the relieving officer of Harpenden, for a medical attendant for Mrs. Howe, a poor woman, aged 40, who was very ill. An order was granted, and forthwith taken by the applicant to the medical attendant; but the latter received no intimation of the urgency of the case: he was not told that Mrs. Howe had small-pox. The part of the parish where the patient resided was five miles

from the residence of the medical practitioner, and it was only the same day that that officer had gone his rounds in Mrs. Howe's neighbourhood. Not until nine or ten o'clock on Friday morning did he visit the woman, in obedience to the order, and then he found her dangerously ill with confluent small-pox. She had, it seems, been nine days ill previous to his attendance. The medical man desired the persons who were with Mrs. Howe to send immediately to his house for medicines, acquainting them with the dangerous condition of the patient. It was not till Saturday noon that a person called at St. Alban's for the medicines; but the patient was already dead: she had expired at six o'clock that morning.

Such are the plain facts—damning enough, in all conscience, of the system under which they occurred. A woman, after struggling for nine days with the fever of variola, of the worst kind, obtains, through the circuitous route of an application to a parish relieving officer, a visit at last from the medical man whose duty it is to attend. He lives five miles off, and urges the friends of the patient to send immediately for the necessary medicines. This is neglected, and the wretched patient dies without any medical succour having been administered to her. What worse could have befallen her in the most uncivilized country? Yet here is England, and its *amended* Poor-Law system!

But if any thing can be worse than the system, it is the conduct of the functionaries who uphold it. We just now complained of the injustice exercised by them in this case towards their medical officer: we have a few more words to say on the subject. It was unjust, we assert, to visit with so much severity (if dismissal from their service be really a severity) the medical attendant who failed to undertake a five miles' journey at a moment's notice, in order

to see a patient, of the nature or urgency of whose case he received no intimation. This, however, is not the worst. It has never been the practice for parish surgeons to *send* their medicines: to expect it to be done in the present case—a distance of five miles—was unreasonable: to make it a charge of breach of contract, was iniquitous. Yet what says Mr. Secretary Chadwick in his sentence of condemnation? "The Commissioners consider that the reason assigned is insufficient, inasmuch as the circumstances under which the pauper was found, her dangerous illness, and the previous neglect (or inadvertence, as the officer represents it), prescribed a deviation from the ordinary practice of waiting until the medicine was sent for by the parties."

How easy it is to preach, even when we forget to practise! The humane Commissioners, of whose humanity we have never yet had a practical instance, think that the state of the unhappy pauper should have quickened the zeal of their officer: and because he did not exhibit more bowels than they ever showed, they have dismissed him.

The most disgusting part, however, of the transaction is the means shuffling practised by the Commissioners, to transfer the blame to the medical man which so evidently belongs to themselves and their system of conduct.

Let the case be a warning to *contractors*; let those who have the ambition to hold the high post of medical officer to a Board of Guardians, be aware of what awaits them should any untoward accident bring the system of *relief* into discredit. Fulfilment of their contract will be insisted on to the letter; and no emergency occurring in private practice may be pleaded in excuse for a neglect of the contract duty. Hear one or two of the interrogatories which we meet with in the present case:—

"But you are aware that your contract is to attend to the parish people, independently of your practice?—This unfortunately happens to be a solitary case. If I had had any idea of the woman's illness, many medical men near me would have gone to see her.

"You are in any circumstances responsible; but in that case, if you had been aware of her illness, and you had not attended, you must be aware what a heavy responsibility, legally as well as morally, you would have incurred: but since you cannot tell with regard to any case that it may not be a dangerous case, you must be aware that it is clearly expected that the attendant should be prompt. And all the instructions you may have received from the Assistant Commissioners, the Guardians, or other persons in authority, must have led you to believe that the attendance under this new Poor-Law would be required to be much more rigid than that required by the parochial officers under whom you have heretofore served. You say you have been accustomed to attend the parish poor for a number of years?—*Yes, for thirty years.*"

The whole case is pregnant with a moral lesson; and if contractors will not mark, learn, and inwardly digest it, they must be lost to all power of ordinary perception. They see here a practitioner of *thirty years'* standing, perfectly familiar with the mode of conducting parish medical relief, yet upon the occurrence of an accident calculated to excite public displeasure, the honourable Commissioners sacrifice him, and throw him overboard!

SIR WILLIAM KNIGHTON.

THE newspapers have already made known the decease of the late Sir William Knighton; and although he had long abandoned medical practice, we think it incumbent upon us to place in our pages some record of one who once belonged to our profession, and whose career has been, in several respects, so remarkable.

Sir William Knighton originally entered the medical profession as apprentice to an apothecary at Tavistock; and after a residence of a few months in

London, returned to that town to settle as a general practitioner. This, however, not proving agreeable to his taste, or satisfactory to his ambition, he soon returned to London, and settled as an accoucheur. The College of Physicians having admonished him for practising as a physician without a degree, he went to Edinburgh, where he remained two seasons; and having obtained a degree from the Archbishop of Canterbury, was admitted a licentiate.

From this time, he remained in London till 1810, when he accompanied the Marquis of Wellesley to Spain, and returned with him when the mission was at an end. On this nobleman retiring from office, he asked his late Majesty to appoint Knighton one of his physicians. Soon after this he became acquainted with Sir John M'Mahon, by whom he was speedily admitted to terms of intimacy; and they continued on the most confidential footing until the death of the latter, who made Sir William his executor. Among the papers which thus came into his possession were some relating to certain private affairs of the late King. Instead of endeavouring to turn this circumstance to any profitable account, Knighton instantly carried the documents to Carlton House, and placed them at once, without comment or condition, in the hands of the rightful owner. From that hour may be dated his admission to Royal favour: the Prince Regent, struck at once with the importance of the benefit and with the delicate manner in which it had been conferred, appointed Knighton to an important office in the duchy of Cornwall;—in 1813, raised him to the baronetage; and, at a later period, presented him with the grand cross of the Guelphic order.

His reputation was now at its zenith, and his business continued very extensive till the removal of Sir Benjamin Bloomfield, who had succeeded Sir John M'Mahon in the office of Private Secretary. On the elevation of this gentleman to the peerage, and his mission to Sweden, Sir William Knighton, who had previously been a frequent visitor, now became an inmate, at Carlton Palace, was invested with the offices of Private Secretary and Privy Purse,—appointments which he retained till the death of George IV.

Before his connexion with the court,

Sir William Knighton practised chiefly, though not exclusively, as an accoucheur. He is said to have been extremely cautious of his reputation—always calling in additional advice whenever there was any manifest danger; and succeeded in amassing a very large fortune by his original profession. From the time of his accepting the appointments above mentioned, he of course wholly abandoned practice; but he still retained an intimacy with several members of the medical profession, some of whom were indebted to him for many acts of kindness and consideration.

He had latterly suffered from embarrassment of the breathing and oppression about the chest, which proved to be dependent upon enlargement of the heart, and ended in dropsical effusion into the right pleura and pericardium, which proved fatal on Tuesday, the 11th instant, in the 60th year of his age.

Sir William Knighton was unquestionably a man of excellent talents, but he was still more conspicuous for his fine sagacity and knowledge of the world. His success in life was remarkable, but such was at one time his interest at court, that it is quite certain he might have commanded almost any thing which the highest influence in the empire could bestow;—yet he never shewed himself either avaricious or greedy of honours. He was scrupulously punctilious in all the observances and etiquettes of society; but, amid the polish which his manners and character received from the circumstances into which he was thrown, he still retained unimpaired the impress of his early friendships.

HOMŒOPATHY.

(From a Correspondent.)

DURING the last two sittings of the London Medical Society, the disciples of Hahnemann have had field-days, or rather nights. The homœopathic orators were three—Dr. Uwins, Mr. Kingdon, and Mr. Headland. They all professed themselves *not* to be homœopaths, *while* they advocated the practice and defended the doctrines of Hahnemann! Dr. Uwins, however, when this inconsistency was alluded to, at the close of the debate, acknowledged that

he was in a *state of transition* between allopathy and homœopathy; but that he was in a fair way to a full adoption of the new light. The homœopathic orators did not practise as they preach on this occasion: they dealt in most enormous allopathic doses of verbiage, but no substantial facts—no rational arguments. They monopolized two-thirds of the time during both nights. The allopathic speakers were—Dr. Clutterbuck, Dr. Johnson, Dr. Rees, Dr. Stewart, and Mr. Clifton. If we can form any judgment of the sense of a most crowded audience by the hearty plaudits which attended and followed the observations of the allopathists, and the peals of laughter which constantly interrupted and sometimes drowned the statements of the Hahnemannians, we should fairly conclude that there was not in the room a single disciple of the “NOVUM ORGANON” except the three speakers above mentioned. The speeches of Dr. Rees and Dr. Johnson caused great merriment by the ridicule with which they covered the principles and practice of homœopathy; while Drs. Clutterbuck and Stewart, in conjunction with Mr. Clifton, demolished the crazy fabric of Hahnemannism by unanswerable arguments. The President himself (Dr. Whiting), at the close of the debate, which he never interrupted in its course, declared his opinion that the homœopaths did not adduce one single fact, either in Mr. Kingdon’s long paper, or in any of their speeches, which could fairly be considered as *evidence* in favour of the new doctrine.

Dr. Clutterbuck then proposed a resolution—that the society, after a patient hearing of homœopathic doctrine and practice, did not consider either of them to be worthy of the slightest attention from a body of enlightened practitioners. The homœopathists loudly objected to the proceeding; and Mr. Kingdon having pathetically remonstrated against it, as calculated to do him a personal and professional injury, as the author of the paper, and consequently the cause of the discussion, several allopathists interfered, and prevailed on Dr. Clutterbuck to withdraw his motion. It was quite clear that not more than three or four hands would have been held up in favour of the infinitesimal system.

It would have been wise, however, in the society, either to have declined the

subject of discussion at first, or to have come to some official conclusion at the end. The homœopathists, acting on their usual tactics, will magnify this discussion into one of the greatest triumphs which Hahnemann has yet obtained in any country! What! the oldest Medical Society in this metropolis arguing the topic for two whole nights, and coming to no conclusion at last, leaving the homœopaths master of the field,—as far as length of speeches, at least, is a criterion!! This is the very course they will pursue, and probably this was the very object they had in view when they entangled Mr. Kingdon in their web, and drew him into the snare, without any but honourable intentions in his own breast. The orators themselves, however, will long remember the miserable display which they made, and the unenviable position in which they now stand before the eyes of their professional brethren.

CLINICAL LECTURE

ON

R H E U M A T I S M.

Delivered at St. George's Hospital, Oct. 13, 1836,

BY DR. SEYMOUR.

Various forms of the Disease: Diffuse and Bursal Rheumatism; Metastasis—Transference of the former to the Heart, of the latter to the Brain. Remedies: Bleeding, Guaiacum, Opium, Calomel, Colchicum.—Rheumatism connected with the Poison of Lead.—Case of Vomica bursting into the Pleura—very large Liver—Gall Stones.

I HAVE been in the habit for many years past of giving clinical lectures at this season of the year. These lectures are simply and solely intended for the use of those students who are beginning for the first time, or nearly so, to attend hospital practice. In order to enable them to understand the views I entertain in treating any disease, I shall describe the disease, and then explain the reasons why particular remedies have been prescribed. I shall place myself as much as possible in the situation I myself was, when a student—desirous of knowing why such and such a remedy was ordered. This is the intention which I wish to fulfil; and I address you, not with the view of making a great display, but of making you comprehend, as nearly and as clearly as possible, the de-

sign with which medicines are prescribed for diseases, the nature of which I shall explain.

There were not many cases admitted on Wednesday last under my care, or any presenting great variety; but there were some which will lead us to make a few observations on a most important disease—rheumatism.

Rheumatic pain is a vague expression. "I think," to use the language of the lower classes, "I have got the rheumatics," means simply that the patient has pains in his limbs. Indeed, I am not sure whether the expression used by the higher classes of society is not equally vague. "I have got the rheumatism," is a complaint we hear every now and then, as applied to wandering pains.

Rheumatism has been divided into acute and chronic; and then there is also rheumatism arising from specific poisons, and rheumatic pains resulting from the introduction of certain metallic fumes into the body. These pains may be produced by the fumes of arsenic; and there is a particular kind of rheumatism—if so it may be called—from the poison of lead. Of the latter there are two specimens in the house, and these, therefore, will give me an opportunity of speaking to you of this disease, and of illustrating my remarks by the cases.

The most severe form, however, of rheumatism is the acute species, *rheumatic fever*, as it is generally termed; and of this we have two very excellent specimens at present—the cases of ELIZA YOUNG, in Crale Ward, and JANE VAUGHAN, in Roseberry Ward.

This disease is one which it is of very great importance in practice that you should understand. There are two kinds of acute rheumatism: sometimes they occur together, and in other cases separately. The cases before us are of the latter description. In one of these patients the muscles, the aponeuroses, and the ligaments of the joints, at the extremities principally, are inflamed. The other is a case in which there is effusion into the cavities of the joints, more especially the wrist, hip, and knee.

It will be of great importance to bear in mind, that the two kinds of acute rheumatism may occur together or separately, because the treatment and phenomena are of an entirely different character. The acute disease which affects the muscles, aponeuroses, and ligaments, with redness and swelling, is very apt to shift from one limb into another. We have a striking instance of it in the case of Ann Young: when she was taken into the hospital the pain was in the right hand; but when I saw her the next day it had left the right

hand, and was seated in the left; and to-day there is no pain at all; it has disappeared. Sometimes it shifts from one hand to the other in a very short space of time, almost in a moment; certainly in the course of half an hour. I have seen it suddenly leave one hand entirely, and affect the foot. This form of rheumatism, for distinction sake, is termed *diffuse* rheumatism, in contradistinction to that which is generally attended with the effusion of fluid.

Diffuse rheumatism is apt to leave an external, and affect an internal, part; or the latter becomes affected without any apparent diminution of the symptoms in the former; or the disease commences in the two parts simultaneously. The affection may occur in these three forms, but it most frequently happens that the pain in the extremities subsides when the internal viscus is attacked: when these symptoms take place it is called *metastasis*. I am not going to enter into any hypothetical views as to whether or not there really is such a thing as metastasis from an external to an internal part; I am merely speaking of the phenomenon as it exists.

The internal viscus, which is almost exclusively affected, at least so far as my experience goes, in diffusive rheumatism, is the heart; though the lungs are said to be sometimes implicated. What takes place is the pouring out of lymph upon the opposite surfaces of the pericardium, by which they are glued together, and the heart is impeded in its functions. In some cases the heart recovers its action, but in others it does not. The effusion occasionally takes place in great abundance, so that lymph is thrown out over the surface of the heart, and is sometimes mixed with pus, and in other cases, though rarely, with blood. This is the condition which is found when sudden death supervenes on an attack of rheumatism, or rheumatism of two or three days' duration. This, however, is fortunately an uncommon occurrence; I do not know that I ever saw a case, though I have read of such, and no doubt they are sometimes met with. Most frequently rheumatism attacks the heart in the course of the disease, and, so far as we can judge, the effect takes place which I have just mentioned—the glueing together of the pericardium and the heart, and the patient recovers, as it were, with a crippled heart—a heart unable to execute its movements. By degrees the cavities enlarge, the circulation becomes interrupted, dropsy supervenes, and at some distance of time the patient dies. Sometimes, on recovering from the rheumatism, the patient is affected with palpitation; a second attack takes place—for it is remarkable how con-

stitutional it sometimes appears to be—and lymph is again thrown out; so that, after death, we may sometimes count the older and later lamina of lymph which have been deposited during successive attacks.

This is the most important view which you can take of rheumatism. You are not, however, to suppose that this often happens; on the contrary, it only occurs in certain cases, generally where the disease has been neglected in the first instance. When the disease has once taken place, though the patient may experience palpitation, distress, and all the inconveniences arising from it, yet he may live for many years, and be liable to successive attacks, until they are so severe as to cause the heart greatly to enlarge, and sooner or later dropsy ensues. Here is a drawing [presenting it] taken from a boy 13 years of age, who died of rheumatism of the heart after repeated attacks. Between the layers of the pericardium, that portion which is reflected over the heart, and that which is opposite, there is an enormous quantity of lymph deposited, which has become organized through the disease having been of long standing.

The danger, then, in acute rheumatism consists in this affection of the heart; and when a man dies under it, the disease will generally be found to have terminated in this way. There are, however, other terminations. The disease may sometimes end in suppuration; but this is not very common; and I have never seen but one case. It much more frequently terminates in a deposition of lymph in the muscles, aponeuroses, and ligaments of the joints, so as to render these parts inflexible.

The two cases under consideration are in the early stage of the complaint: one patient has been ill for a fortnight, and the other, according to her own account, has only suffered from rheumatism two or three days.

The great object in the treatment of this disease is to extinguish the complaint without the changes taking place to which I have referred—the attack of an internal viscus. The treatment divides itself according to the form which the disease has assumed, and the part which has become attacked. Sometimes where the heart is not affected, as in the cases up stairs, there is great pain, which is sometimes increased and sometimes diminished by heat, affecting generally the hands and feet, sometimes the shoulders and knees; a very quick pulse, a furred tongue, and considerable heat of skin are present—in fact, fever. Blood, when drawn early in the disease, is generally much buffed and cupped; as much so as in any febrile disease with which I am acquainted. For instance, VAUGHAN, who

has only been labouring under the attack a few days, was bled as soon as she came in, and the blood was buffed and cupped. The disease still being severe, I had the venesection repeated, and the blood was again as much cupped as in inflammation of any serous membrane. I must, however, warn you, that experience has shewn that it is not good practice to continue bleeding in the same proportion as in inflammation. You may go on bleeding a rheumatic patient, where the blood is buffed and cupped, with the hope of diminishing it, and yet you will find it present till death ensues. But, on the other hand, I should warn you against withholding the use of the lancet in the early stages of the disease. There was no question in the profession discussed so much as the propriety of bleeding in rheumatism, especially after Dr. Haygarth's paper. It was looked upon by some physicians that bleeding, notwithstanding the state of the blood, was the cause of the transference of the disease to the heart. I can only state, from my own experience, after many years spent in this hospital, and the practice which I have seen in other places, that if in cases of acute rheumatism, with symptoms such as I have described, where there is much inflammation, with a quick pulse, and great heat of skin, you do not use the lancet early, you will have cause to repent it; though the time will come when it would be highly improper to resort to it. It is a severe form of the disease where we are obliged to have recourse to it; and in VAUGHAN'S case I have been compelled to bleed twice. She is a young woman, very robust; and the relief has been commensurate to the loss of blood. YOUNG had been bled before she came in, and it was not a case for me to resort to it. The pulse was 100; the patient was not strong, indeed she was pale from the loss of blood; and there was no heat of skin. At first one hand was swollen: subsequently the other became affected; and to-day I find, after the treatment adopted, that neither hands are swollen, and the rheumatism is subsiding with great rapidity.

There are various modes of treatment on which physicians have determined, for the cure of diffusive rheumatism in which the heart has not become diseased, and the affection is in its early stage. The treatment I have been in the habit of pursuing, is to exhibit (after bleeding, where that is requisite) the guaiacum mixture. This is prepared by rubbing down guaiacum with gum arabic, and then adding to it cinnamon water, and sugar. If you mention this to persons who have not tried it, they will tell you that rheumatism is an acute disease; thinking you mean

the ammoniacal tincture (a medicine much in use in chronic cases); but this tincture is of a stimulating nature. The mixture which I have mentioned has a powerful effect in relieving the rheumatic symptoms; at least, in my experience it has been very great. I must have seen fifty cases cured by this method, and cured as quickly as by any other means which I have either used or witnessed. An ounce and a half of the *mist. guaiaci* of the Pharmacopœia may be given every four hours, together with barley water. The medicine determines to the skin, producing a sudorific effect on that organ, and likewise acts on the bowels. Sometimes it acts too powerfully on the latter, and then it is necessary to give a grain of opium at bed-time. Under this treatment, combined with the use of the lancet, and keeping the patient on low diet, I have, in a great number of instances, seen the severe form of acute rheumatism give way. I have never, in a single instance, to the best of my recollection, seen metastasis occur in the progress of the cure. I am not telling you of a new or recent practice, for these are the remedial means which I have pursued for eight or nine years. I first learned this method in Edinburgh, where I found it more resorted to than any other mode of treatment in the clinical wards of the hospital. I do not know that it will cure a patient more quickly than calomel and opium, but calomel and opium make the mouth sore and affect the bowels, whereas this is attended by no such consequences. When the woman was admitted, who had been ill a fortnight, I had some fear of an affection of the heart, and I administered calomel and opium; but finding that that was not the case, I changed the medicine, and to-day the report is as satisfactory as it can be. There is no swelling of the hands, the tongue is moist, there is much perspiration from the medicine, the bowels are open, and the pulse 106. The other case is more severe; but as it is only of two days' standing, I have not yet ascertained the effect of the medicine. She still continues under treatment, and you will have an opportunity of observing its influence upon the disease.

This is a form of the complaint in which the heart has not become affected—in which we have the patient in the acute stage; and I can recommend this practice as being as certain of curing the disease as any particular mode of treatment is in any other affection. But suppose the case comes in with the heart already attacked—then this treatment is not sufficient. The patient, in this case, should be bled; but in a small quantity, and in the recumbent posture, because syncope is apt to take

hand, and was seated in the left; and to-day there is no pain at all; it has disappeared. Sometimes it shifts from one hand to the other in a very short space of time, almost in a moment; certainly in the course of half an hour. I have seen it suddenly leave one hand entirely, and affect the foot. This form of rheumatism, for distinction sake, is termed *diffuse* rheumatism, in contradistinction to that which is generally attended with the effusion of fluid.

Diffuse rheumatism is apt to leave an external, and affect an internal, part; or the latter becomes affected without any apparent diminution of the symptoms in the former; or the disease commences in the two parts simultaneously. The affection may occur in these three forms, but it most frequently happens that the pain in the extremities subsides when the internal viscus is attacked: when these symptoms take place it is called *metastasis*. I am not going to enter into any hypothetical views as to whether or not there really is such a thing as metastasis from an external to an internal part; I am merely speaking of the phenomenon as it exists.

The internal viscus, which is almost exclusively affected, at least so far as my experience goes, in diffusive rheumatism, is the heart; though the lungs are said to be sometimes implicated. What takes place is the pouring out of lymph upon the opposite surfaces of the pericardium, by which they are glued together, and the heart is impeded in its functions. In some cases the heart recovers its action, but in others it does not. The effusion occasionally takes place in great abundance, so that lymph is thrown out over the surface of the heart, and is sometimes mixed with pus, and in other cases, though rarely, with blood. This is the condition which is found when sudden death supervenes on an attack of rheumatism, or rheumatism of two or three days' duration. This, however, is fortunately an uncommon occurrence; I do not know that I ever saw a case, though I have read of such, and no doubt they are sometimes met with. Most frequently rheumatism attacks the heart in the course of the disease, and, so far as we can judge, the effect takes place which I have just mentioned—the glueing together of the pericardium and the heart, and the patient recovers, as it were, with a crippled heart—a heart unable to execute its movements. By degrees the cavities enlarge, the circulation becomes interrupted, dropsy supervenes, and at some distance of time the patient dies. Sometimes, on recovering from the rheumatism, the patient is affected with palpitation; a second attack takes place—for it is remarkable how con-

stitutional it sometimes appears to be—and lymph is again thrown out; so that, after death, we may sometimes count the older and later lamina of lymph which have been deposited during successive attacks.

This is the most important view which you can take of rheumatism. You are not, however, to suppose that this often happens; on the contrary, it only occurs in certain cases, generally where the disease has been neglected in the first instance. When the disease has once taken place, though the patient may experience palpitation, distress, and all the inconveniences arising from it, yet he may live for many years, and be liable to successive attacks, until they are so severe as to cause the heart greatly to enlarge, and sooner or later dropsy ensues. Here is a drawing [presenting it] taken from a boy 13 years of age, who died of rheumatism of the heart after repeated attacks. Between the layers of the pericardium, that portion which is reflected over the heart, and that which is opposite, there is an enormous quantity of lymph deposited, which has become organized through the disease having been of long standing.

The danger, then, in acute rheumatism consists in this affection of the heart; and when a man dies under it, the disease will generally be found to have terminated in this way. There are, however, other terminations. The disease may sometimes end in suppuration; but this is not very common; and I have never seen but one case. It much more frequently terminates in a deposition of lymph in the muscles, aponeuroses, and ligaments of the joints, so as to render these parts inflexible.

The two cases under consideration are in the early stage of the complaint: one patient has been ill for a fortnight, and the other, according to her own account, has only suffered from rheumatism two or three days.

The great object in the treatment of this disease is to extinguish the complaint without the changes taking place to which I have referred—the attack of an internal viscus. The treatment divides itself according to the form which the disease has assumed, and the part which has become attacked. Sometimes where the heart is not affected, as in the cases up stairs, there is great pain, which is sometimes increased and sometimes diminished by heat, affecting generally the hands and feet, sometimes the shoulders and knees; a very quick pulse, a furred tongue, and considerable heat of skin are present—in fact, fever. Blood, when drawn early in the disease, is generally much buffed and cupped; as much so as in any febrile disease with which I am acquainted. For instance, VAUGHAN, who

has only been labouring under the attack a few days, was bled as soon as she came in, and the blood was buffed and cupped. The disease still being severe, I had the venesection repeated, and the blood was again as much cupped as in inflammation of any serous membrane. I must, however, warn you, that experience has shewn that it is not good practice to continue bleeding in the same proportion as in inflammation. You may go on bleeding a rheumatic patient, where the blood is buffed and cupped, with the hope of diminishing it, and yet you will find it present till death ensues. But, on the other hand, I should warn you against withholding the use of the lancet in the early stages of the disease. There was no question in the profession discussed so much as the propriety of bleeding in rheumatism, especially after Dr. Haygarth's paper. It was looked upon by some physicians that bleeding, notwithstanding the state of the blood, was the cause of the transference of the disease to the heart. I can only state, from my own experience, after many years spent in this hospital, and the practice which I have seen in other places, that if in cases of acute rheumatism, with symptoms such as I have described, where there is much inflammation, with a quick pulse, and great heat of skin, you do not use the lancet early, you will have cause to repent it; though the time will come when it would be highly improper to resort to it. It is a severe form of the disease where we are obliged to have recourse to it; and in VAUGHAN's case I have been compelled to bleed twice. She is a young woman, very robust; and the relief has been commensurate to the loss of blood. YOUNG had been bled before she came in, and it was not a case for me to resort to it. The pulse was 100; the patient was not strong, indeed she was pale from the loss of blood; and there was no heat of skin. At first one hand was swollen: subsequently the other became affected; and to-day I find, after the treatment adopted, that neither hands are swollen, and the rheumatism is subsiding with great rapidity.

There are various modes of treatment on which physicians have determined, for the cure of diffusive rheumatism in which the heart has not become diseased, and the affection is in its early stage. The treatment I have been in the habit of pursuing, is to exhibit (after bleeding, where that is requisite) the guaiacum mixture. This is prepared by rubbing down guaiacum with gum arabic, and then adding to it cinnamon water, and sugar. If you mention this to persons who have not tried it, they will tell you that rheumatism is an acute disease; thinking you mean

the ammoniacal tincture (a medicine much in use in chronic cases); but this tincture is of a stimulating nature. The mixture which I have mentioned has a powerful effect in relieving the rheumatic symptoms; at least, in my experience it has been very great. I must have seen fifty cases cured by this method, and cured as quickly as by any other means which I have either used or witnessed. An ounce and a half of the mist. guiaci of the Pharmacopœia may be given every four hours, together with barley water. The medicine determines to the skin, producing a sudorific effect on that organ, and likewise acts on the bowels. Sometimes it acts too powerfully on the latter, and then it is necessary to give a grain of opium at bed-time. Under this treatment, combined with the use of the lancet, and keeping the patient on low diet, I have, in a great number of instances, seen the severe form of acute rheumatism give way. I have never, in a single instance, to the best of my recollection, seen metastasis occur in the progress of the cure. I am not telling you of a new or recent practice, for these are the remedial means which I have pursued for eight or nine years. I first learned this method in Edinburgh, where I found it more resorted to than any other mode of treatment in the clinical wards of the hospital. I do not know that it will cure a patient more quickly than calomel and opium, but calomel and opium make the mouth sore and affect the bowels, whereas this is attended by no such consequences. When the woman was admitted, who had been ill a fortnight, I had some fear of an affection of the heart, and I administered calomel and opium; but finding that that was not the case, I changed the medicine, and to-day the report is as satisfactory as it can be. There is no swelling of the hands, the tongue is moist, there is much perspiration from the medicine, the bowels are open, and the pulse 106. The other case is more severe; but as it is only of two days' standing, I have not yet ascertained the effect of the medicine. She still continues under treatment, and you will have an opportunity of observing its influence upon the disease.

This is a form of the complaint in which the heart has not become affected—in which we have the patient in the acute stage; and I can recommend this practice as being as certain of curing the disease as any particular mode of treatment is in any other affection. But suppose the case comes in with the heart already attacked—then this treatment is not sufficient. The patient, in this case, should be bled; but in a small quantity, and in the recumbent posture, because syncope is apt to take

place. Considerable doses of calomel and opium should then be given, the object of which is to arrest the progress of the deposition of lymph; and if exhibited in sufficient quantity, it frequently produces this effect. I have seen patients in the most perilous condition, with a disposition to syncope, with a quick and irregular pulse, and sinking of the countenance, put under the operation of five grains of calomel and one grain of opium three times a-day, with the effect, in four or five days, of diminishing all the symptoms. These are cases which I have witnessed over and over again. The quantity of mercury which may be given during the disease, without doing more than arresting the symptoms, is quite remarkable. I remember a case which I saw, under the late Dr. Young, in which the patient took ten grains of calomel daily, in acute rheumatic pericarditis, for fifteen or sixteen days, and never at any time did the mouth become sore. This is one of the instances in which I have frequently had occasion to point out the effect of medicine on disease. If the patient were in health, a fiftieth part of the mercury would produce constitutional effects; but here the power of the remedy is expended on the disease. This is well known in many cases, but it cannot be better illustrated than in this instance.

I have spoken of two forms of rheumatism—more diffuse rheumatism, and diffuse rheumatism transferred to the heart. Where no transference has occurred (I use that term because it is a simple word, though the disease may occur without any evidence of the transference), and, in the second form, where it has already taken place, various persons have different methods of treatment: some treat the acute form with blood-let and antimonials, others with calomel and opium, and it is a common practice with some to exhibit colchicum combined with Dover's powder, as a sedative.

It sometimes happens that this disease lasts a great length of time; the heart is not attacked, and yet the patient does not recover. This constitutes what is called an *intermittent* case, and presents itself once, perhaps, in twenty or thirty instances of the affection. The patient has perhaps been bled, taken colchicum, and also calomel and opium, and yet the disease rolls on, and in other instances he has not taken any of these things—he has not taken medicine at all, in any considerable quantity—and the disease is still severe. The patient, in such a case as this, complains of violent pain, the surface is pale, and in addition to that, there are constant sweats breaking out over the body, which are of an acid character, and accompanied with acute pain. The pain is aggravated

by warmth, rather than relieved by it. When such is the case, we have a remedy the effect of which is quite magical: a grain of opium, administered every four hours, will sometimes entirely cure this form of the disease in a way hardly credible. Some years ago, I saw a case which might be called one from constitutional disease: it occurred in a lady, thirty-five years of age, who was attacked with severe rheumatism in the summer. The case was the more alarming from the fact that she was one of a family three of whom died of rheumatic pericarditis in early life; but she never had any symptoms of the disease till she was thirty-five. She was bled, and the usual remedies were applied, with some measure of relief; but still the disease went on, and neither calomel and opium, nor guaiacum nor colchicum (for the case was treated, in the first instance, as an inflammatory disease), was of the smallest service. A consultation was held, and I met Dr. Nevins, who recommended, as the patient had been ill a month and the disease had but little abated in violence, though it had sometimes left her for a few hours, that a grain of opium should be given several times a-day, which had the desired effect. Some of you have seen cases in the hospital treated in the same way, and with the same success. The cases where you must have recourse to it, are where the pain is very severe—where it has continued some time, is not relieved by warmth, and is accompanied by this acid perspiration.

I should say something on the employment of colchicum. Colchicum has been considered useful in rheumatism, and I will describe the particular form in which it is beneficial—viz. synovial rheumatism. It may sometimes be of service in the diffuse form, but it as often fails; I think, oftener. In cases where the heart is attacked, I have, in my experience, had to repent its employment. It knocks down the vital powers, and the pulse becomes exceedingly irregular, so that it is best not to give it in this form of the disease; but in another variety it is very useful. In the diffuse form I have seldom seen the good effect of colchicum. Once, in a severe form, complicated with effusion into the joints, the expressed juice, with opium, was of great benefit: but in no other form is it so useful and decidedly beneficial, as in synovial rheumatism.

I stated that there were two kinds of rheumatism—that it affects the muscles and the joints; and these may occur together or separately. In the cases under consideration there is no effusion into the joints; but in a case up stairs, fluid has been rapidly effused into them, without

affecting the muscles or tendons. When this is the case, there is a difference in the symptoms, which I shall point out; a difference in the march of the complaint and in the method of cure. By making this distinction, you simplify the practice very materially.

In synovial rheumatism the lancet is not so much required as in the diffuse kind; and here colchicum, as I have said, is exceedingly beneficial. I have seen it in many cases. I had a case last summer, entirely cured, in a very short space of time, by colchicum alone. There are various forms in which it may be employed. Half a drachm of the vinum colchici may be given in camphor mixture, and half a scruple of magnesia is generally added. Some suppose, from the acidity that is present, that there is a separation of the colchicum wine and a throwing down of a sediment, on which its benefit depends; and this is prevented by the magnesia. This may be given twice a day, or three grains of the acetic extract with five grains of Dover's powder. In the majority of instances you will relieve this form of the complaint.

I told you that the march of the disease was different, and I will explain why. This form is sometimes transferred to an internal viscus; but the cases in which this takes place do not bear the proportion of one to forty, compared with the transference of diffuse rheumatism to the heart; and when an internal organ does become affected, it is the brain, and not the heart. This is worth bearing in mind. Unfortunately, it is not uncommon to see rheumatic pericarditis; but fortunately it is very uncommon to see affection of the brain from the transference of synovial rheumatism. I have only, in my own experience, seen five cases—four in private practice and one in the hospital; whereas, in the same space of time, I have seen fifty cases of the other form of the disease. This shows you how very important it is to comprehend it. A case of the transference of synovial rheumatism to the brain, took place in the hospital last spring. A man came into the hospital, in whom some of the joints were as large as a child's head, from effusion, and he was in a perfectly cachectic state of body: there was a white tongue, with little appetite, and no fever. He had taken colchicum for some time, without manifest advantage. I thought the best plan appeared to be to put him on a tonic medicine, as he was in such a cachectic state, and to bring up the constitution so that he might bear other remedies. For this purpose he was ordered bark, and I gave him a little meat, but no porter—nothing stimulating: indeed the full diet of the hospital is not so much as persons eat in ordinary life, in health.

He appeared to be somewhat better. I one day observed the knees becoming flaccid, and, in fact, they were reduced one-half in size. He was attacked with violent pain in the head, there was palsy on one side, and within the space of thirty-six hours he died.

Upon opening the body, it presented a remarkable appearance. Over the left hemisphere of the brain there was deposited a thin layer of green purulent matter, so as to cover it over, and some fluid was found in the ventricles. Never at any period before or during the attack was there any symptom of that increased action which generally precedes a paralytic attack. Here was one form of rheumatism transferred to the brain. In using the word *transference*, let me again mention that I only wish you to understand it in the common acceptance of the term: I am by no means giving it as my opinion that the disease is transferred from one situation to another, but that upon the cessation of it in the joints this affection takes place in the brain. This is as clear as I can make the subject. The two diseases may occur together or separately, and there is a distinction in the symptoms, the treatment, and the termination. The remedies which are applicable to the one are not so applicable, if applicable at all, to the other. But you may have complicated cases, in which there is diffused inflammation, together with effusion into the joints; and in these cases, adding to the ordinary treatment some preparation of colchicum is generally of great service.

You will watch the cases to which I have referred, and I think you will see that the cure will be very rapid.

There is a case in Crayle Ward of a woman who came in with rheumatism of the joints, and I point out the case in order to show you one of the terminations of this synovial rheumatism. She entirely recovered with the exception of one knee-joint. You will sometimes have this occur: the patient will recover with the exception of one joint, which is more inflamed than the others, and some stiffness remains. The case is now nearly cured, and will, I have no doubt, get perfectly well.

There is also a case in the hospital, under my care, of chronic rheumatism. It is one in which a slight acute attack has passed over, but there is still great difficulty in moving the limbs, from some remains of pain in the joints. It is the case of an old woman in Roseberry Ward. She is 70 years of age, and laboured under fever from cold, since which time she has had diminished power of the lower extremities. This is marked to show that it does not depend on an affection of the brain, but on rheumatism, which has

ended by impairing the powers of motion. It affected her hands and knees. As the bowels were not opened, I ordered her to be purged, and then to be placed in the vapour bath. This leads me to mention the great utility, in some cases, of this practice. The being able to administer these baths readily, is one of the greatest modern improvements. There is one upstairs, in addition to which they may be brought to the bed of the patient, and copious perspiration may be readily excited. They are an excellent substitute for the external use of Bath water, which is so effectual in most cases.

In the chronic form of the complaint, the fever having disappeared, the warm and the vapour baths are useful; but because they are serviceable in rheumatism, have a care not to recommend them in the acute form, for, so far from being applicable to it, on the contrary fatal results may take place. I have known disease of the heart ensue after a blunder of this kind; and I have known them bring on a state of great excitement and fever, instead of the febrile action being diminished. The bath acts as a stimulus in the acute form of the disease, and is therefore contraindicated. In the chronic form, where the parts have lost their elasticity, and where fever no longer remains, to such a condition are they applicable.

There were also two other cases admitted, to which, being of a different kind, I shall call your attention. They are cases arising from the introduction of a morbid poison into the system—the poison of lead. One case is that of a man named CLANEY, a coach-painter, who is lying in York Ward. He has been subject to the complaint for six years. The joints are neither affected with redness nor swelling; the bowels are constipated, and there is a cachectic state of the countenance, arising from his employment. He has been under medical treatment, without relief, for many weeks. The other is the case of REDDING, in Hope Ward, who is suffering under a more advanced form of *colica pictonum*, with slight palsy of the hands.

I will explain what is the effect of lead taken into the constitution. What is the first impression, I cannot exactly say, but the symptoms which follow are, pains of the limbs, loss of appetite, great degeneration, as it were, of the general health, and the patient looks as if there was no red blood in the body. If he still continue to work at his employment, contraction takes place in the muscles of the abdomen, and probably in the muscular coat of the intestines, and the bowels are drawn back, so that when you place your hand in that region, you appear almost as if you touched the spine. There is obstinate

constipation under this form of the disease. This, as I have said, is termed *colica pictonum*. The word *pictonum* has been first derived from the inhabitants of Poitou, a province of France, and the disease was first described by the physician to Cardinal Richelieu, in the time of Louis the Thirteenth. It was proved to depend upon acid wine being made in leaden vessels. The wine dissolved a small part of the oxydized lead, and the persons who drank of it were affected with the disease. As it occurs in persons who work in lead, and very frequently in painters, it is sometimes supposed that *pictonum* is the Latin for painters. This is the most general form of the disease, and then it is termed *painter's colic*. If the patient has suffered one or two attacks, and still continues to work in lead, after a time palsy of the extensor muscles of the fore-arm takes place, and the hands drop. If even after the restoration of these the man still remains in the same employment (and what this poor man told us is often the case—that if he did not work in lead he had no other means of obtaining subsistence) various symptoms take place—epileptic fits, and an affection of the bronchi, with expectoration, very similar to phthisis. Sometimes, likewise, there is effusion into the joints, which is called rheumatism from the poison of lead. I remember having in the old hospital three cases at one time in one ward, in which there was synovial rheumatism arising from the poison of lead. In a very old work, called Musgrave on Rheumatism, you will see several cases well described. At the present time we have only two cases, one labouring under general pains from the poison of lead, and the other suffering under colic; and we have the commencement of palsy, the bowels very costive, the extensors of the fore-arms paralyzed, the abdominal muscles drawn in, and of course when there is an endeavour to make the bowels operate, there is very great pain.

In this instance the cure is most generally allotted to some purgative, combined with opium, to relieve the spasm, and followed up by castor oil, which is, of all other remedies, the one best adapted to effect a passage in such cases as the dry belly-ache in the West Indies, where the disease arises from making rum in vessels with leaden cramps, and in Devonshire, from making cyder in such utensils. After a free passage has been obtained, the warm bath should be used; and when the patient's health becomes better, great stress has been laid on the use of balsam of Peru, and consequently I am in the habit of giving it when convalescence is commencing. It strengthens the muscular fibres which have been affected.

You will be enabled to watch these two

cases, and I have no doubt that they will both recover. In the worst case the palsy has not gone to a great extent. Some recommend placing the hands on a splint, so as to give support to the extensor muscles. I have seen this practice pursued, and I think with some good effect. It was recommended by the late Dr. Pemberton, of this hospital. You will find in the Transactions of the College of Physicians some interesting papers on the effect of the poison of lead, by the late Sir George Baker, who took great pains in investigating the Devonshire colic, and discovered that it was owing to this solution of lead, effected by the action of a vegetable acid upon the troughs in which the cyder was made.

I think that I have laid before you a good number of points for your consideration as you go round the wards. I have explained my reasons for the remedies which have been laid down, and the general circumstances in the cases to which your attention should be directed.

On Friday next I shall take up some other point, describing, in the first instance, what has been the progress in those diseases to which your attention has now been called.

Before you leave me, I beg your attention to some morbid appearances brought for your inspection. The patient in whom these were found was under the care of my colleague, Dr. Macleod. You will see the account of the symptoms during life in his case-book, and he will readily afford you any further information.

There is a vomica in the right lung, which has perforated through the pleura, pouring out fluid into the right cavity of the chest, through the aperture, which is rather larger than the circumference of a split pea. There were found no less than 125 gall-stones in the gall-bladder, which you see here—one nearly as large as a walnut, the others much smaller. When these little bodies are pressed forward, so as to obstruct the duct, jaundice often takes place, with violent pain at the epigastrium and in the back, with frequent vomiting, and a *slow pulse*. This constitutes what is termed bilious colic. The liver, you will also observe, is double its natural size, and, in fact, occupied a large portion of the abdomen, reaching to the crest of the ilium; and yet there was no dropsy. The worst cases of ascites, as I shall have occasion to show you, do not arise from enlarged livers, but in consequence of the liver being uniformly contracted, often to half its natural size, and the peritoneal coat is usually thickened in patches.

I have thought it desirable to give you an opportunity of examining these appear-

ances, though I must refer you to the physician under whose care the patient was for an account of the symptoms during life.

ST. GEORGE'S HOSPITAL.

Ligature of the External Iliac Artery.

On Thursday last (20th), the external iliac was tied, at St. George's Hospital, by Mr. Walker, for femoral aneurism. The operation was very skilfully performed, and there is every reason to expect that the patient will do well.

UNION OF THE EASTERN WITH THE GENERAL PROVINCIAL ASSOCIATION.

To the Editor of the Medical Gazette.

SIR,

THE tone of your remarks upon my last communication induces me to give you early intimation of the fulfilment of my wishes with regard to the junction of the Eastern Provincial Medical and Surgical Association with the General Provincial Association.

This, I consider, was effected on Wednesday last, at a meeting of the Council of the late Eastern Society, in Norwich, when it was unanimously resolved, that "its members do immediately join the parent Society, on the terms proposed by the Council of that body, through Dr. Hastings."

Thus one hundred and sixty, or seventy, members will be at once added to this excellent, useful, and flourishing Society; and I feel convinced the South of England will speedily imitate our example, and that the practitioners of England will be connected in one great and powerful body, admirably adapted to defend the profession from all the attacks which individuals, or the legislature, may make upon its respectability or rank, and to promote its scientific and successful cultivation.

Hoping that you will take an early opportunity of making this junction known to your numerous readers, in any way most congenial to your feelings,

I remain, sir,

Your obedient servant,

J. GODWIN JOHNSON.

64, St. Giles's-street, Norwich,
Oct. 14. 1836.

MORE PLURALIST LECTURERS.

To the Editor of the Medical Gazette.

SIR,

IN the last number of his journal, that most disinterested and impartial person

the *honourable* M. P. for Finsbury, has attacked the Aldersgate School on the plea of some of the teachers lecturing on more than one branch. They do so; but had not Mr. Pereira's admirable lectures been published in the *GAZETTE*, and had not Dr. Cummin's, which promise to be equally valuable, been now in progress, I dare be sworn Mr. Wakley's virtuous indignation would have slumbered. As, however, he has mooted the subject, I must request him to look at home; and he will find in his own school in Gower-street, precisely what he condemns elsewhere. With his usual dishonesty he misrepresents facts,—separating and announcing as distinct courses what is given in one and the same course in every school in London. Such, for example, as Therapeutics, which he makes a distinct course from *Materia Medica*; Theory of Physic distinct from the Practice, and so on of others;—the purpose being to make it appear that there are twice as many courses as lecturers!

Now, sir, according to Wakley's method of reckoning, his new *protégé*—his Magnus Apollo (for the present season)—lectures on five different subjects; and according to the most favourable mode of reckoning, does actually give *three* totally distinct courses; thus:—

Therapeutics Dr. A. T. Thomson!

Materia Medica . . Dr. A. T. Thomson!!

Medical Jurispr. . Dr. A. T. Thomson!!!

Toxicology Dr. A. T. Thomson!!!!

Clinical Medicine, Dr. A. T. Thomson!!!!

“There's a display for you!” (*Vide Lancet.*)

Again, his *pet*, Dr. Grant, stands much in the same predicament as his colleague, Dr. Thomson, as appears by the published advertisements—thus:—

Comparative Anatomy Dr. Grant.

Zoology Dr. Grant.

Geology (a part of the course), Dr. Grant.

Fossil Zoology (separately advertised) } Dr. Grant.

Not to mention—

Physiology (at his own house), Dr. Grant.

nor his engagements to lecture at other schools. So much for Wakley's impartiality! “They who live in glass houses,” Mr. Editor;—but the proverb is rather musty.

Your obedient servant,
AN ALDERSGATE PUPIL.

October 17, 1836.]

CAMBERWELL PRACTITIONERS AND THE POOR-LAW MEDICAL CLUB.

To the Editor of the Medical Gazette.

“All seems infectious that the infected spy,
As all looks yellow to the jaundiced eye.”

SIR,

It is not my intention to follow a late correspondent of yours through the elegant terms of his vocabulary; it is quite evident that he is a “stickler against the clubbists.” I am sure that you will not feel surprised that I have no desire to see my name put forward with, probably, the title of *knave* or *king of clubs* in your next number. I would willingly shield myself from that honour; but, in deference to your opinion I will throw off the mask, and will ask any unprejudiced mind to view the situation of those two practitioners (Messrs. Flower and Young, of Camberwell Green, the latter a partner of Mr. Forbes), each paying rates to the collector (Mr. Prebble, of Camberwell), whether they may not fairly be termed Camberwell practitioners. I think the letter in the same column, from Mr. Bowen, sufficient to set that matter at rest. And now to the question—“Can he show us how this innovation will benefit the poor man?” I reply, certainly not; as there is nothing so impervious to argument as the blindness of prejudice—

“A man convinced against his will,
Is of the same opinion still;”

but I presume there are many cool and reflecting minds to whom I may address myself with more prospect of success. Is it, I ask, no benefit to a poor man to have placed within his reach the option of selecting, from the general practitioners of a neighbourhood, his own medical attendant, and not be compelled, for fear of incurring to him a ruinous bill, to have recourse to the parish surgeon?

Ask the man of principle, whom a reverse of circumstances has driven to the threshold of despair, and who is but a few stages removed from the workhouse, with a wife or some of his children lying on a bed of sickness, whether he feels it a benefit to be able to avoid this first step to pauperism (*viz.* having recourse to the parish surgeon), but to have placed within his reach a number of practitioners, upon whose kindness and attention he has a positive claim? and I fear not to hear his reply. I venture to say there are but few medical men so “fallen,” as to consider themselves degraded by attending this man's family, or to be scared from their duty by

having applied to their name the paltry term *clubbist*. I envy not the feelings of such men. Yes; there are those, constituting, too, a numerous class of professional men, who consider it no degradation, no dishonour to the professional character, to lend their assistance in endeavouring to raise the *moral condition* of the poor, by cherishing that feeling of *independence* which has been too much neglected, and which, I had almost said, was a national blessing; and they are not to be deterred in contributing their *mite* to this object, from a feeling that had they acted differently, they might perhaps have screwed out the last shilling from the wretched sufferer. True it is, that we may occasionally get a bill of two or three pounds from the honest and industrious poor; who, if we could witness the deprivation both themselves and families endure rather than apply to the parish surgeon, it would add but a fresh proof, if any were wanting, that it needs no argument from my pen to convince the spectator of this scene; that it is *indeed a benefit*, and will be *felt and estimated as such by the poor*; and that it *will not, cannot*, tend to injure and degrade the profession. With such an object in view, let us lay aside all party feelings; and if we are not able to appreciate or feel that it is a benefit to the poor, we are at full liberty to decline giving it our support; but let us have the modesty not to apply to those who differ from us in opinion terms of the grossest abuse; and pray let us hear no more about “shedding the last drop of blood in the cause.”

The plan has also the further recommendation of acting on the principle that the man who does the *work* shall have the *pay*. Now it is a well-known fact, that hitherto the profession generally have been in the habit of giving their advice and medicine to many of the poorer classes in their respective neighbourhoods; considering the parish surgeon, from the extent of his district, the numerous calls to which his situation subjects him, the addition of his private practice—to say nothing of the prejudice too often entertained against him; these, with other causes too numerous to mention—such as the repeated applications made to private practitioners by women in a state of actual labour, who, either from aversion to the parish surgeon, her own neglect in not applying for an order; the fear lest, when it is obtained, he will not attend himself, but send some youth; these, with other reasons which my time will not permit me to enumerate, cause a considerable number of midwifery cases to be thrown upon the hands of private practitioners, who do not receive even the small sum to which the parish sur-

geon is entitled for his attendance—to say nothing of the answers she sometimes receives to her application during her hour of trial; one desiring her to apply to the parish surgeon, another asking who is to pay *me* if I come. In the meantime she is perhaps confined, and the child or children, as it may be, for want of timely assistance, are dead, and the life of the woman endangered. To remedy these evils, “let the man who does the work have the pay.” I shall not stay to inquire whether to such poor it will be a “benefit,” or to ask the medical man whether, by being paid, *he feels degraded*. For myself, I have given to the plan much of calm and quiet deliberation, and perceive it in active, useful, and *unopposed* operation in many of the provincial districts; and however strongly this measure may be opposed by some, there are not wanting from among the ranks of the profession many who think, under judicious limitations, the proposed measure may be usefully, nay, profitably, adopted; by the poor man, as a means to obtain assistance suited to his circumstances—by the practitioner, as obtaining *small but certain remuneration*.

And now a few words as to the interest of the medical man; and on this head I need only ask the practitioners living in the immediate neighbourhood of a dispensary, with the abuses to which it is subject, whether it is not a far more objectionable measure, and fraught with much greater danger to the interests of the private practitioners, and much more likely to take the bread out of the mouths of the poorer class of surgeons, than the formation of a Medical Club, with the “concerted measures of the Forbes’s, the Beans, the Brownes, and the Flowers” of any district? I feel satisfied that had Mr. Bowen been acquainted with more than the *mere* names of those persons he has mentioned, he would never have imputed to them being actuated by such unworthy motives.

I have now only, in conclusion, to call your attention to an advertisement, in which I find that it is intended to try the effect of a good dinner upon the general practitioners of Southwark and its vicinity, to cultivate among themselves that unanimity and good feeling so essential at the present period, in consequence of the many recent attempts to *injure* and *degrade* the profession,—at which, doubtless, many good things will be both *said* and *swallowed*; and though I leave them to the enjoyment of this method of “*mutual protection*,” with the cheers, the triumph, and the hollowest exultation, and though no garland flaunt around my recreant head, I shall rest contented with the homely and humble festa¹

board of co-operation in a good cause, and be solaced by the recollection of my humble but well-meant endeavours, and in the satisfaction arising from the possession of the "*mens conscia recti*."

With these hurried remarks, not intending again to trouble you on this subject, and thanking you for your impartial conduct, I take my leave, "throwing off the mask," and avowing myself a "Camberwell Practitioner"—

J. S. FLOWER,
Surgeon.

Camberwell Green,
Oct. 17, 1836.

PROCEEDINGS IN CAMBERWELL.

REPLY TO MR. HULBERT.

To the Editor of the Medical Gazette.

SIR,

I READILY comply with Mr. Hulbert's request; and as this matter concerns the profession generally, and especially the practitioners in this district, you will, I trust, give insertion to *all* my statements, as I am prepared to prove their correctness. I will pass over the "wigs and gold-headed canes of antiquity," and also the letter of the "Camberwell Practitioner" (which appears to be Mr. Hulbert's chief prop), and only allude to one insinuation contained in his letter, viz. "that I am acting under the direction of others." Such an inuendo would excite anger in my mind, if I believed that any individual except Mr. Hulbert could entertain the same opinion; but as it emanates from him alone, I can readily excuse it. "*Il y a des reproches qui louent, et des louanges qui médisent.*"

And now for my justification of the personalities I am accused of.

At the Camberwell meeting Mr. Hulbert made the following statement:—"I am sure I do not wish to act in opposition to my professional brethren." Now, sir, from the whole tenour of Mr. H.'s proceedings, I thought that he was not actuated by this feeling; and the following circumstances induced me to form that opinion:—Mr. Hulbert came into this neighbourhood a few months since, I believe, a perfect stranger. I had the honour, on the 4th of August, to receive a circular from him, inviting the "*clerical* and medical professions, and others, to attend a meeting at the school-room in this parish, for the purpose of hearing Mr. Smith, on the subject of "Self-supporting Dispensaries," J. Callaway, Esq. in the chair. A

very small number of these circulars, however, reached the members of the *latter* profession; and Mr. Hulbert's excuse for this omission was, "that his boy was unable to find the residences of the medical men, and therefore returned the circulars."

This meeting was adjourned till September the 7th, when I found Mr. H. siding with men who characterized the members of our profession "*as gross and mercenary conspirators; who told us to read our bibles, and mark well the story of the good Samaritan; that we were only a fraction of the community, and must yield to the public good,*" &c. Mr. H. afterwards wrote to the Editor of the *Surrey Standard*, calling his account of the meeting *impartial*, when he knew that the reporter only gave the arguments of those who were favourable to the plan.

At a subsequent meeting, when a large body of medical men were present, a letter was read by Mr. Hulbert's son, from Mr. Hawes, M.P., stating, "that if the medical practitioners were consulted, that this Dispensary could not be formed; but he (Mr. H.) recommended its formation without paying any regard to their opinions." After the above, I think that I was justified in descending to personalities; and, when speaking of the clubs and dispensaries, I thought it desirable that the gentlemen present should know how these things were managed in the borough of Southwark and its vicinity; and I made the following observation:—That Mrs. Hulbert was in the habit of walking about from morning till night recommending the "Self-supporting Dispensary;" and on that very day she had called upon a lady in Trinity Square, and, amongst other advantages, had held out as an inducement, that the servants might become members." But, sir, this remark was levelled at Mr. H., and not at the lady, as I presumed that she acted according to her husband's directions.

And, lastly, to shew that the general practitioners in this neighbourhood are somewhat interested in Mr. H.'s movements, I may state that a handbill (printed in the same type and character as those issued by Messrs. Eady and Co.) has been circulated, addressed to the industrious mechanics and working classes of the borough of Southwark and its vicinity; the writer of which (after speaking *à la Rowland* "of a discerning public, and promising these said industrious mechanics, that, under the Divine blessing, all their ills will be removed,") offers them physic, &c. for 1d per week; male servants to pay 7s. per annum; female, 5s. do. &c.

"Persons desirous of becoming free members may apply for information to Mr. Hulbert, 6, Trinity Square, any morn-

ing between the hours of 10 and 12, Sundays excepted "

I must apologize for having occupied so large a space in your journal, but I have, in *self-defence*, been obliged to enter into the above explanation.

Yours respectfully,
E. CRISP.

Walworth, Oct. 18, 1836.

NEW REGISTRATION OF BIRTHS AND DEATHS.

To the Editor of the Medical Gazette.

— "O miser! quæ tanta insanla, cives?
Creditis avertos hostes? aut ulla putatis
Dona carere dolis Danaum? —
— equo ne credite, Tæcrici,
Quicquid id est, timeo Danaos, et dona ferentes." VIRG.

SIR,

I WAS much gratified by your remarks in the GAZETTE of the 3d instant, on the "dainty device of Mr. Secretary Chadwick, and his employers, for degrading the profession into a Company of Parish Clerks." I felt persuaded that the tone and spirit of your observations would be justly appreciated by every one anxious for the interests and character of the profession.

The Poor Law Commissioners, it seems, have very generously offered to the worst-paid and hardest-worked officers of the Unions—members of a profession they have sought every opportunity to insult, injure, and degrade—the *very lucrative and highly dignified* office of subordinate, or district, registrar of births, deaths, and marriages, "when these duties are not inconsistent with their engagements, and they may be disposed to perform them!" Discreet, delicate, generous men, with large salaries, "small brains, and no bowels!"

Such conduct of the Commissioners, whose general treatment of the profession has deservedly excited in the minds of all its respectable members feelings of unqualified disgust, being characteristic, is not much to be wondered at; but I am surprised that your correspondent, T. G., should think it "extraordinary" that medical men have, in so many instances, refused the *very respectable* office of subordinate registrar, encumbered as it is with duties, and productive as it is of emoluments, so well suited to the taste, time, attainments, and expectations, of a parish clerk. I confidently believe that he will hear of many more instances of men, who, considering what is due to their profession, and to the cool impudence of the Somer-

set House triumvirate, and their scribe, will have rejected this contemptible offer.

If the medical profession is to be benefited, we may be sure it will not be at the hands of the Poor Law Commissioners, but by the united exertions of its own members; nor is it necessary for the advancement of the statistics of medicine, that medical men should accept the proffered honour.

It was very well known that the "bait" would be taken only by those who cherish and are charmed with the "credit" of an appointment by a Board of Guardians—Mr. Chadwick's neophytes, the "wider field officers" of the Poor-Law Commissioners.

A correct registration of the number and causes of deaths may be effected, and all the desired advantages derivable therefrom may be obtained, by the medical profession, without a voluntary and spiritless submission on its part to more injustice and new indignities.

Let the Commissioners and the Guardians appoint their relieving officers—persons in their estimation perfectly qualified to judge of the degree of illness of paupers, and of the necessity of medical aid, or any other persons whose engagements are not incompatible with the duty, and let them procure from the friends of the deceased, in writing, under the hand of the medical attendant, a statement of the known or supposed cause of death. Any respectable scribe may transfer this to his register.

To this it must come, if accuracy be intended, appoint whom they may. A district registrar, even if a medical man, could not, unless omniscient, ascertain with the requisite precision the known or supposed cause of death without a direct or indirect appeal to such medical authority.

T. G.'s wonder, I think, should cease or abate on further consideration; for he needs not to be assured that the medical profession are fully aware of the ceaseless endeavours of the Poor-Law Commissioners to degrade general practitioners into a race of petty pedlars and parish clerks, and they, consequently, are able to appreciate their present politeness. The profession can, and assuredly will, afford their efficient aid in promoting the objects of the Registration Act, as far as they are, or ought to be, concerned; but they are not to be expected to seek degradation, or voluntarily suffer injustice, upon even so specious a pretext.—I am, sir,

Your constant reader,

JUSTITIA.

Camberwell, Oct. 19, 1836.

DR. UWINS AND DR. J. JOHNSON.*To the Editor of the Medical Gazette.*

SIR,

UPON mutual explanations being given, Dr. Uwins has entirely absolved me from the charge of having written the article copied from the GAZETTE into the *Times*, and, consequently, has absolved the Editor of the GAZETTE from the charge of breach of veracity. This *absolution* (grounded, however, on the charge being owing to a mutual misapprehension), was publicly given in the London Medical Society last Monday night. I have written to the *Times*; but as some delay may take place in the appearance of my letter, I request you will give these few lines a place in your next number.—I am, sir,

Your most obedient servant,
JAMES JOHNSON.

NOTICES.

"R." 1. No law, right, or charter, would be violated. If the party did not pretend to be a *Doctor*, he would not come under the jurisdiction of the College of Physicians; if he did not dispense medicines, the Society of Apothecaries could not interfere with him. He would be *quasi* a Surgeon, and the Royal College of Lincoln's Inn have not the power to question any one.—2. The proposed University is not to interfere with the College of Physicians, which cannot be superseded unless by a special act of Parliament,—a measure which there is no reason to suppose will be attempted, and if attempted, would certainly fail in the upper House.—3. Not till after the meeting of Parliament.—4. In the *MEDICAL Gazette* for Sept. 17, 1836.

We must decline the publication of Mr. Marson's letter.

CHARING CROSS HOSPITAL.—We understand that this hospital has been struck off the list of those recognised by the College of Surgeons.

The P.S. from Camberwell came too late.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE V.

On Sex, medico-legally considered—Importance of the subject: 1. Normal development—Characteristics of the Male and Female Figure—Male and Female Skeleton. 2. Abnormal development—in the Male—in the Female—where the Sexual Characters are mixed. Hermaphroditism—remarkable cases—all resolvable into Androgynous and Gynandrous varieties. Concealed Sex—some modern instances.

SEX, like Age, is a subject of wide extent and application. It not only forms an element in other medico-legal inquiries, but frequently becomes an independent question. As medical jurists you may be called upon to give evidence as to the sex of an individual—infant or adult—living or dead; nay, the sex of the foetus may sometimes be a moot point.

It may also be necessary sometimes to identify the supposed remains—the mutilated relics, of a person long missing. It may be that only the bones are found. Here the sex requires to be clearly ascertained: we must be assured that we do not take the bones of a male for those of a female, and vice versa.

Legal distinctions.—In the case of a new-born child, the determination of the sex may be of vital importance, if it be the issue of parents possessed of real or landed property: its right of succession mainly depends on its sex; and should it die, the disposal of that property, which it

would have enjoyed as a male, must be arranged in accordance with the evidence of the sex. The interests of many expectant relatives may be at stake.

In reference to tenancy by the courtesy, the right of the father to possess a life interest in the real property belonging to his wife, may depend on the ascertainment of the sex of their new-born infant. For if the wife be tenant in tail male, and delivered of a son born alive, the husband's right is secured; whereas, if she have only a daughter, the husband is not entitled to be tenant by the courtesy, because such issue was excluded from succession by the nature of the tenure. This is a fact which ought to be fixed in the memory of every practitioner who happens to be present at the birth of a child belonging to persons of property; indeed, in every case it would be proper for the accoucheur to note the circumstances of the birth, particularly with regard to the sex of the infant. But I shall have occasion to revert to this subject more fully hereafter.

Again, at an age more advanced—childhood—the arrangements regarding the education and future prospects of the young person are essentially founded on an understanding of the sex: it would be a serious mistake to give (as has been done) the education of a female to one who should afterwards prove to be a male. Dr. Beck cites a case in which a physician was consulted by the relatives of a young nobleman of doubtful sex, who, if a male, would inherit a considerable estate, but to which he could have no right if he belonged to the other sex.

Now, in ordinary cases, it may seem to be a very simple affair to determine the sex—whether the subject be an infant, an adult, or merely a skeleton. But we shall see that difficulties may sometimes arise; and this not only where the sexual characteristics are abnormal, but even where they are normally developed.

I. NORMAL DEVELOPMENT.

Suppose, in the first place, that the sexual parts and other peculiarities of the male or female are normal. No difficulty, of course, will present itself to us, provided we be allowed the opportunity of personal inspection—more particularly if the subject be an adult, or have attained the age of puberty. The ordinary sexual characters of individuals at the different periods of life need not detain us.

Sex before birth.—But there are one or two cases, even in the normally developed condition, in which it may not be very possible to speak without deliberation regarding the sex. There is a period, for example, in intra-uterine life, when the sex is by no means determinable. The foetus, up to a certain age, possesses no distinctive sexual parts: those that are observed might prove, upon further development, to belong either to the male or female. If we examine the foetus, or embryo, as early as the fifth or sixth week after conception, we shall find that the rudiments of the genital organs have not yet made their appearance; and that it is not till somewhat later that a little tubercle becomes visible; which tubercle may prove subsequently to be either a clitoris or a penis: as yet, at all events, there are neither labia nor a scrotum. This condition holds for the first fifty-five days, according to Velpeau.

At from eight to ten weeks, the tubercle undergoes further development. Around its base there arises a fold of integument, the rudiment of the future prepuce; and a little furrow is perceived on its lower part, which soon after forms the urethra. This furrow, which remains unclosed for some time in certain foetuses, extends to within about a line of a little prominence,—the anal tubercle: for as yet the anus is imperforate, and merely presents the appearance of a slight elevation. In short, it is probably not till about between the second and third month that any thing can be positively stated relative to the sex of the normally developed foetus.

Sex of the new-born child.—It may happen that at a much later period—that of birth—doubts may be entertained whether the sex be ascertainable; for the testes may not yet have passed through the abdominal rings, and the scrotum may be imperfectly formed. The progress of the descent of the testes is curious. From their original situation, a little in front of the kidneys—where also the ovaries are primarily situated—they descend by about the seventh month towards the inner ring, carrying before them the fold of peritonæum, which afterwards constitutes the tunica albuginea. In the eighth, they enter the passage, and during

the ninth are generally deposited in the scrotum. Upon an examination of ninety-seven infants at birth, Wrisberg found that in sixty-seven both testes had reached the scrotum; in seventeen, one or both were still in the canal; in eight, one testis, and in three, both testes still remained in the abdomen.

At later periods.—Let me now call your attention to some other cases of possible difficulty in determining the sex, although there be nothing abnormal about the proper characteristics, so far as they are developed. Suppose we have to examine a skeleton—one that probably belonged to a person not yet adult. In such a case, though we may be possessed of the elements for determining the age, the sex is by no means so well marked as to be readily distinguished. The skeletons of infants and young persons of either sex, have few or no peculiarities by which the necessary investigation may be guided. We must here call to our aid whatever external circumstances may be available for the information which we seek.

But when we have to examine what appears to be an adult skeleton, with reference to sex, there are several characters of which we may avail ourselves. Let us first take a view of the female as distinguished from the male figure.

The adult figure in both sexes.—There is, in general, more plumpness in the female form than in the male. The muscles are smaller, and less strongly marked; the integuments are more abundant, and softer; and the cellular substance is more largely provided with a supply of fat. The nails are smooth and semi-transparent, the hair of the head fine and long; and that on other parts of the body comparatively scanty.

The proportions also present some remarkable contrasts. Thus the female is usually not so tall as the male; half her length corresponds to the upper part of the symphysis pubis, while, in the man, the half is situated at the middle of the symphysis. In the female, accordingly, the lower extremities are comparatively shorter than in the male. The head is generally smaller; the lower jaw and chin less marked and prominent. The teeth, smaller and whiter, sometimes do not exceed the number of twenty-eight. The neck slender, with little or no projection of the larynx. The trunk somewhat longer, enlarged in its upper and anterior part by the prominence of the breasts, and the position of the arms, which are in closer contiguity with the sides than they are in man. The posterior aspect of the trunk presents a furrow, extending to the sacrum; while the la-

teral parts usually exhibit a depression on either side, from the ribs to the hips, peculiar to the female, more especially as modified by the civilization of the present day. The chest of the female has a larger antero-posterior diameter than that of man; but a smaller bi-costal or transverse diameter. The hips and upper part of the thighs comparatively more round and extended; the knees are more inclined inwards; the leg is shorter, and the foot more small and delicate. The shoulders are narrower than the hips; while the reverse holds in well-formed men. The arm and fore-arm are more round, but less marked, than in the male; the hand is smaller, and the fingers more tapering.

Bones of either sex.—With regard to the osseous structure, it may be observed that there are some very striking peculiarities belonging to the bones of the female; they are less firm, and lighter than those of man. The flat bones are thinner, and the short ones more cellular or spongy; the long bones are more smooth and tapering, nor are there perceived on them those rough lines or ridges, which result from the repeated and more powerful action of the muscles in the male. The apophyses, which afford attachments to the muscles and ligaments, are but feebly marked: the joints are generally less large, but more flexible, than in

the male. The ligaments and cartilages are more pliant, and continue so for a longer period. And, in short, we every where discover in the general structure traces of a more delicate conformation.

Male and female skeleton.—But to come more particularly to the parts of the skeleton:—The cranium of woman is smaller, more oblong, and less depressed on the sides than that of man; the face more oval; the frontal sinuses less developed; the nasal apertures smaller; the jaws, with the alveolar arches, are shorter and more elliptical; and the chin is not usually prominent.

The shape of the chest has been already noticed; but it may be added, that the sternum is shorter and more convex; the xyphoid cartilage is thinner and more flexible, and remains unossified for a longer time than in the male. The ribs are also more delicate and uniform; the cartilages which join them to the sternum are longer and more elastic, and their dorsal articulation less compact: thus the female chest is comparatively more largely endowed with the power of expansion and contraction than the male.

The pelvis.—Both the shape and size of the pelvis are remarkable. Here are representations of the male and female pelvis, showing the distinctive characters.

FIG. 6.—Female pelvis.

FIG. 7.—Male pelvis.

The *osæ ilia* in the female (fig. 6), it will be observed, are more spread out, or verging to the horizon, than in the male. The sacrum is more capacious and concave; the pubis less elevated, and its ascending branches forming a less acute angle; the *osæ ischia* wider apart; the subpubic foramina larger, more oblique, and approaching a triangular shape. The various symphyses of the pelvic bones are less compact than in the male, and allow more motion. The following are the diameters of a well formed, we may call it a *standard*, female pelvis: it may be observed, by the way, that they are considerably larger than those of the male:—

Of the inlet, the antero posterior diameter measures 4 in. 4 lin. English; the transverse, 5 in 5 lin.; and the oblique, 5 in. Of the outlet, the antero-posterior diameter measures about 5 in.; and the transverse, 4 in. 4 lin.

The cotyloid cavities of the female pelvis are more distant from each other than those of the male, giving rise to a remarkable difference in the position and appearance of the femurs; these bones being in woman much more oblique from without inwards than in man. The neck of the thigh-bone is more transverse, and the trochanters more apart, than in man. The inner condyle, also, is

larger, and a little longer, than the exterior, which gives rather a peculiar aspect to the female knee.

The chest, as seen from behind, is narrower and less convex in the female than in the male; it is shorter, also, so that there is a greater space between the ribs and the crest of the ilium.

In fine, the vertebral column is more flexible, and somewhat longer, comparatively, than in man. The vertebræ are less compact; the spinous processes less prominent; the transverse more turned backward. The body, or anterior portion of the vertebræ appears (to Soemmering) to have more height; but at all events the intervertebral cartilages, especially in the lumbar region, are thicker, softer, and every way larger, during pregnancy.

Illustrative case.—By way of illustration of the remarks just made, I may refer to a case hereafter to be more fully noticed. A parcel of bones, forming a skeleton, having been disinterred a year or two since in Paris, one of the first questions which the medico-legal examiners proceeded to solve was, whether these were the bones of a male or a female? I quote from the *Annales d'Hygiène* (tome xi. 137) that part of the official report relating to this subject:—"The bones are small and delicate; those of the extremities not at all curved by muscular motion: the marks of the insertion of the muscles are few and faint. The cranium is small, and oblong from front to rear. The ossa innominata are largely spread out; the cavity of the pelvis not deep; the anterior of the sacrum concave; the subpubic holes triangular; the cotyloid cavities wide asunder: finally, the upper strait of the pelvis presents exactly the diameters usually found in well-shaped females. So that, putting all these characters together, there cannot be a doubt but that this is the skeleton of a woman."

II. ABNORMAL DEVELOPMENT.

We have next to consider how the sex may be determined in persons who have an abnormal development of the generative organs. Here we may have considerable difficulties to contend with in our inquiries, especially if the individual be living, as we are thereby in great measure precluded from an internal examination. Sometimes the male organs may be so formed as to simulate at first view those of the female: the female organs, again, may have such a conformation as to mislead a superficial observer, and induce him to believe them male. But this is not all: there may be an actual mixture of the male and female organs in the same person, giving rise to the supposition of hermaphroditism. We shall consider these varieties in order.

1. *Abnormal development of the male.*—Some men have the orifice of the urethra opening, not at the usual place—at the extremity of the glans—but somewhere beneath it,—perhaps as low down as the root of the penis. Such persons are called Hypospadians (*ὑποσπᾶδαι*,—imperfect beings, *σπᾶδῶνες*, with the orifice, *ὑπο*, beneath); and their true sex is apt to be confounded owing to this additional circumstance:—in some of them, the penis being wholly imperforate, resembles an enlarged clitoris; and in such cases it commonly happens that the orifice of the urethra being beneath, the scrotum is divided, forming two distinct sacs, with a testicle in each, thus presenting the appearance of enlarged labia. Suppose, now, in a person of such a conformation, that the testes have not descended or emerged from the abdominal rings (as happens in some men), and let the penis be diminutive, it will be easily understood how striking may be the resemblance to the female organs.

When the orifice of the urethra happens to be any where *above* the usual place, either on the glans or on the dorsum, or even the abdomen, the person so formed is termed an Epispadian (*ἐπισπᾶδαις*, the peculiarity being *ἐπι*, above). I mention this variety of conformation, however, at present, merely for the sake of contrast. Epispadia is not a peculiarity which can tend to render the sex very ambiguous, though, like Hypospadia, it materially interferes with the generative function. Of both, in reference to this circumstance, I shall have occasion to speak in a subsequent lecture, when I shall also notice some other malformations of the male genital organs.

Persons in whom the testes have been atrophied or wasted away, sometimes present the external characters of the female, though belonging decidedly to the male sex. Sir Everard Home tells us of an idiot boy, aged 13, who had no penis, but in its stead a prepuce of small dimensions, beneath which was observed the orifice of the urethra. In the scrotum, which had no raphé, were found two very small testes, not larger than those of a foetus. The mons veneris was very plump. Vagina there was none; but the whole body was exceedingly fat, and the breasts were as large as those of a bulky woman.

A very remarkable and well-authenticated case was published some years ago in a French periodical (*Bull. de la Faculté de Paris*, No. X.) In the year 1792, an infant newly born was registered and baptized as a female, by the name of Marie-Marguerite. On attaining the age of puberty, two small tumors made their

appearance at the inguinal rings, and being mistaken for hernia, it was attempted to repress them by trussing; but all in vain—they came down into the labia. At the age of 19, Marie-Marguerite was about to be married, when it was thought advisable first to examine those tumors, lest they might prove any impediment to matrimony. All this time nothing more than a mere hernial affection was suspected. What, then, was the surprise of all parties when the professional examiner, Dr. Worbe, pronounced Marie-Marguerite to be a man!

Among the reasons assigned by the Doctor for such a conclusion, it is mentioned that there was something masculine in the shape, stature, and voice of the individual, as well as about the hands and feet. The breasts, however, were in some degree developed like those of a female. As to the parts of generation, there was nothing external to indicate that they were those of a male. But upon examining the labia, or what were considered as such, the testes could be felt in a manner admitting of no mistake. There was nothing very remarkable about the size or situation of the supposed clitoris: there was, however, no vagina, for what at first appeared to be that passage, was found to terminate at the depth of

about an inch and a half in the orifice of the urethra. It was, in fact, a well-defined case of hypospadias.

M. Dupuytren (*Lapous orales*) knew an extraordinary instance of this kind. A person affected with hypospadias was married for fifteen or twenty years, and during all that time was treated as a female. Sexual intercourse was regularly effected by the canal of the urethra; nor was it until the period just mentioned had elapsed that it was discovered—the individual was a man!

About two years ago I saw a person of this description—one Gottlich, a German, who came to exhibit himself to the faculty in London. He had little more of a penis than the glans, and the scrotum was divided so as to resemble labia: there was, however, a testicle on each side; and the general appearance was much more that of a man than of a woman. He was about 35 years of age, and pretended to have strong sexual propensities—for the male*.

2. *Abnormal development of the female.*—We have next to consider what are the circumstances and external characters of structure which may render a female liable to be confounded with the male sex.

In the first place, the clitoris may be excessive in its dimensions, when it will resemble an imperforate penis.

FIG. 8.—*Abnormal Sexual Development in a Female Infant.*

Here is the representation of an enlarged clitoris in a child that lived many weeks. It was not till after death that the mistake was discovered: the infant having been baptized as a boy. The uterus (C C), by which the preparation is partly suspended, serves to show the sex. The clitoris (A) bears a close re-

semblance to the penis of a male child of the same age, except that the prepuce does not completely cover the glans. At the extremity of the glans there is a sul-

* An account of this person, with an engraving, is given in the *Edinburgh Medical and Surgical Journal* for 1835, vol. xiii.

cus, but it terminates in a *cul-de-sac*, and does not form the entrance of the urethra*.

In the next place, the general appearance of the person may be more or less masculine; as in a case observed by Beclard, where the resemblance in structure went so far as that the urethra ran for some distance along the lower surface of the clitoris; rather a rare variety. This person, however, (her name was Marie-Madeleine Lefort) had a decided vagina, menstruated, and moreover had the sexual desires of a female.

In cases where females labour under that distressing malformation, *ectrophia* (εξ and στρεφειν)—the bladder turned outwards, opening, in fact, on the abdomen, or at least above the symphysis pubis—the cervix uteri may be thrust forward out of the vulva, and present the appearance of a male organ. A portion of the intestine also has been known, under the same circumstances, to protrude above the pubis, and to put on a similar appearance.

A prolapsed uterus, congenital or accidental, may sometimes simulate the male organ. This was the case with a French woman, who exhibited herself and pretended so be as much a man as a woman; but Saviard succeeded in restoring the womb to its place. Sir Everard Home mentions an instance of the protruded cervix, in which the investing membrane, from long exposure to the air, had assumed the external character of the penis.

3. *Mixture of the male and female organs.*—But beside the malformation in either sex, just now described, there are undoubted instances on record of the parts of the two sexes being in some measure mixed, in one and the same individual. These are the cases which serve to support the vulgar notion of

Hermaphrodites.

Such a being, however, as a true hermaphrodite—that is to say, a person capable of impregnating and of being impregnated—has never yet been discovered among the human race. Whenever there is found a combination of this sort in an individual of our species, it generally happens that the organs of neither sex are complete—that the person is unprolific; at all events, that at least one set of the sexual apparatus is wholly inert.

There is a case narrated by Maret, in the *Mem. de l'Acad. de Dijon*, tome ii., which has been much quoted—it is that of Hubert-Jean Pierre, a person aged seventeen, who was female in the upper part of the body, and male in the lower; female, again, on the right side, and male

on the left: yet, after all, was neither perfectly male nor female.

But in general there will be found to be more or less of the predominance of one sex. If the male characteristics are more strongly marked than those of the female, the individual is termed *androgynous*: if the reverse, *gynandrous*. And I believe it will be found that all the well-authenticated cases on record may be reduced to one or other of these varieties.

Professor Mayer, of Bonn, has lately had the opportunity of solving a problem which interested the physiologists of Europe for upwards of thirty years. He has removed the veil which so long hung over the mysterious case of the "*hermaphrodite Durrge*," or *Derrier*. This person was a Prussian, was christened as a female, but considerable doubts about her real sex were entertained after having reached the period of puberty. Durrge travelled a good deal between the age of twenty and forty, and was inspected by most of the *savans* in Germany, France, and England. Opinions were greatly divided. Hufeland pronounced the prevailing sexual character to be feminine; Oslander considered it to be male; while Gall affirmed that it was decidedly feminine. "The so-named Carl Derrier," said Gall, "ought, if called after his sex, to be named Caroline Derrier. The structure of the head is that of a woman, long from before backward; the forehead low and small. Although he is now thirty-seven years old, [this was in 1817,] he has no beard, and his voice is that of an elderly woman. His larynx is small; the arms and knees are bent inwards, as in the female sex; the breasts are larger, in proportion to his size, than would be consistent with the development of a man. The hips are those of a woman: in short, the structure and proportion of the whole body bespeak the woman. The enlarged clitoris is not placed over a scrotum, so that it cannot be called the penis of a man; it is placed rather between the labia, as in the female organs. . . . The organ which he possesses does not, as in man, arise behind the arch of the pubis, which alone would serve to show that he is not a *hypospadian*, as the Parisian faculty have supposed. Whether or not he possesses a womb, cannot be decided till after death."

Durrge was an ingenious person: he had learnt the art of modelling in wax, and executed several excellent specimens for different museums. In his fortieth year (1820), he settled at Bonn, where he obtained the appointment of wax-modeller and inspector to the anatomical Museum. He died of apoplexy, in March, 1835, being then 55 years old.

* Ramsbotham; *MEDICAL GAZ.* vol. xiii. 184.

For the last fifteen years of his life, he had been under the immediate observation of Professor Mayer; so that this gentleman had ample opportunity of noting both the moral and physical peculiarities of the case. From the account given by the Professor, in the *Wochenschrift für die gesammte Heilkunde*, of Berlin*, I shall make a few extracts.

"He always carried himself as a man, probably through vanity; and showed an inclination to females, but without any decided impulse which would make his prevailing sex more certain. His character was a mixture of manly and womanish qualities. For his small growth, he possessed unusual courage and muscular strength; he exhibited also a good deal of mechanical dexterity. His voice, though it grew stronger and deeper with age, was but shrill and weak; his beard grew sparingly, and all his hair fell off, excepting a few long ones on the back of his head. His head and countenance were those of an old woman, and with these corresponded the want of teeth, the short neck, the breast, so abundantly supplied with fat, and the position of the arms and feet. In his twentieth year there was a discharge of blood from the genital organs, repeated three times. Since then there had been no trace of it, but he has frequently had discharge of blood from the nose. * * *

His body was fully developed in his thirteenth year: he was five feet in height. * * * In his thirty-eighth year he became fat, and his voice grew stronger and deeper. He was generally healthy and active. But in the last three years of his life, his memory, which had been always very good, failed him: he became altered, and gave up his wax embossing. His death occurred rather suddenly."

I shall pass over most of the details of the anatomical inspection: but some passages relating to the genital organs in particular, cannot be omitted. "The *mons veneris* is slightly arched, and but scantily provided with hair. The length of the penis to the corona glandis is two inches: the glans measures nine lines. The corpora cavernosa are moderately developed, being eight lines in perpendicular diameter, and four transverse; separated, too, by a septum. But there is no corpus spongiosum. The urethra, constituting a sort of semi-canal by folds continued from the labia, at its commencement about the root of the penis, is surrounded by the prostate gland, which body is decidedly firm, though not very thick. The length of the vagina is two inches and eight lines; its width anteriorly ten lines, and posteriorly

six. It terminates in a sort of spongy tissue, from four to six lines in length, which is, in fact, the closed orifice of the uterus. This organ, though lying between the bladder and rectum, is rather turned towards the left side; it measures two inches three lines in length, but is very narrow in proportion. The cervix and fundus may be distinguished. The cavity of the uterus very small, scarcely admitting a large quill, widening, however, towards the fundus. Both the fallopian tubes open regularly into the womb—the left an inch shorter than the right: their canal very narrow, but perfect. Upon the right side, close to the abdominal end of the fallopian tube, there is a small flat oval body, about the size of an almond, and corresponding in structure to a testicle. On the left side, however, a small body similarly placed, exhibited traces of the texture of an ovary."

The Professor's opinion, in conclusion, is, that this was an instance of a mixture of the sexes—"that there was a union of the male and female characteristics in the development of the individual. The principal male peculiarities in Durrge were the withered testicle, the penis, and the prostate gland; while on the other hand, the uterus, the vagina, the fallopian tubes, and the ovary-like body found on the left side, all bespeak the woman."

M. Bouillaud's case.—About three years ago M. Bouillaud read before the Paris Academy of Medicine a curious account of what he called "a new and singular variety of hermaphroditism." It was the case of an individual who died of cholera in La Pitié, and whose body, on examination after death, exhibited very anomalous appearances. Nothing more was known of the person but that he was a widower, 62 years of age, a dram-drinker, a hatter by trade, and Valmont by name. He had no relations or friends, nor could anything be gathered as to his habits of life, propensities, manners, or intellectual capacity: "as if nature," says M. Bouillaud, "were in some sort ashamed to reveal the mystery of so strange an aberration."

The condition of the genital organs will be readily understood from the figures here displayed. But first let us describe the exterior. In the region of the sexual parts there was a penis of moderate size, terminated by a well-formed glans and prepuce. The opening, however, of the urethra was not exactly at the summit, but a little below the usual situation. The scrotum small, commencing as high up as the prepuce, and divided symmetrically by a raphe; but no testicles contained within. The *mons veneris* was rather round and plump. In the pelvis were two ovaries (11 and 12, fig. 9.),

* See also MEDICAL GAZ. vol. xviii. p. 217.

FIG. 9.

similar to those of a girl of fifteen or sixteen years of age. M. Bouillaud, however, contends that the texture of these bodies was intermediate between that of ovaries and testicles—rather fibrous than vesicular. The uterus (10) in its usual place, opening into a vagina (8), about two inches long; this passage contracts (15) about the neck of the bladder, and runs into the urethra. A regularly-formed prostate gland (2, 2, in fig. 10) is observed about the commencement of the urethra. No ejaculatory ducts could be observed; and, like the testicles, the vesiculæ seminales and vasa deferentia are wanting. "No external female organs."

Other characteristics noted in this remarkable person were, that the stature was short, the body plump, the hands and feet small, the pelvis shallow, and wider than is usual in man; the mammary glands much developed, and the nipple of the common size in healthy females.

M. Bouillaud thinks that this individual was a sort of *meto-terme*, or *juste milieu*, between man and woman,—a real hermaphrodite, however incomplete. But I should be strongly disposed to differ from him—the female organs being so very predominant throughout, and those attributable to the male so very open to question. In fact, with the exception of the doubtful testes, and the prostate (which some recent anatomists do not consider as exclusively peculiar to the male), all the rest were the parts of a female abnormally developed, or of a *gynandrous* individual. If we only imagine the clitoris large, the urethra carried along it to the glans, and the labia closed by a raphé, we come very near a similar conformation. I have mentioned the case, however, under the head of mixed development, partly through deference to the authority of M. Bouillaud, and partly because the external appearances were so equivocal; for Valmont, during life, must have greatly puzzled a medical jurist, had he been submitted for personal inspection.

Dr. Handy's case.—There is not, perhaps, any case on record, more nearly approaching the state of genuine hermaphroditism, than that described by Dr. Handy, in the New York Medical Repository. This gentleman saw, at Lisbon, a person twenty-eight years of age, of a masculine and dark aspect, furnished with some beard, but having the larynx, voice, and manners of a woman. The external genital organs of both sexes were present. Those of the male were well proportioned, and apparently complete, with the exception of the urethra, which seemed to terminate at about a third of its length. The female organs were well formed, save that the labia seemed smaller than natural. The thighs were not large: nor were the hips broad. This person menstruated regularly, and

FIG. 10.

was twice with child, miscarrying on both occasions—once in the third, and the second time in the fifth month.

It would have been well in this case to have ascertained, had there been an opportunity, the condition of the *internal* genital organs. Externally, nature seems to have gone to the furthest limit which she ever allows herself in varying the structure of the human being; and had we merely been permitted a casual inspection, without a history of the person, particularly with reference to the menstrual function and the pregnancies, we might probably have been much at a loss in giving an opinion.

Practical rules.—This suggests the importance of having some practical rules whereby we may be guided in our investigation of such cases.

When the person to be examined is merely a hypospadian, or has the male organs malformed in the superficial resemblance of those of the female,—also where the individual presents an enlarged clitoris, or other malformation of the female at first sight simulating the male parts,—in such cases there cannot be a great deal of difficulty if we only use ordinary care in making our inspection. But when the organs are obviously mixed, much embarrassment may be experienced. The following are the practical precepts given by M. Marc, and recommended by Orfila:—

1. The examination of all the external organs must be performed with exactitude and caution: every opening is to be sounded, to ascertain its depth and direction—taking care to use no force.

2. The whole exterior of the body must be inspected, with a view to determine the prevailing character, and hence the probable sex. This, however, will often require time: we cannot immediately become acquainted with the tastes, habits, and propensities of the individual under examination; and care must be taken in this respect not to confound the habits which may have originated in the artificial position held by the party in society for those that result from organic structure or development.

3. Ascertain whether from any opening, especially about the sexual parts, there be any *periodical* sexual discharge,—a circumstance of great importance, and which will be of itself almost decisive as to the feminine nature of the person examined.

4. When the individual submitted to our scrutiny is very young—suppose a new-born child with irregular sexual organs—nothing is more likely to mislead than precipitation. We must avoid haste by all means. Perhaps the utmost we can, or ought to do, in the first instance,

would be to give a formal notice of the dubious nature of the case, and to take time—years, if necessary, in order to be able to observe the progressive development of the physical and moral characteristics: this we should deliberately do, rather than hazard any opinion which subsequent facts may stultify.

5. No attention ought to be paid to the declarations of the individual himself, or of persons who have ties of relationship with him: at all events it will be necessary to weigh well such declarations, in order that we may form a correct judgment of the possible motives by which they may be dictated.

Legal distinction respecting hermaphrodites.—Let it not be supposed for a moment that the subject of hermaphrodites is one of merely physiological interest, or of only a speculative value to the medical jurist. As medical men professing to be acquainted with the proper objects of Forensic medicine, we may be called on in the courts, civil or ecclesiastical, to give our opinion regarding the true sex of a reputed *hermaphrodite*. The law, in fact, recognises the existence of such beings, and it is expressly stated by the highest legal authority (Coke, Littleton),—"An *hermaphrodite*, which is also called *androgynus*, shall be heire, either as male or female, according to that kind of the sexe which doth prevaile. *Hermaphrodita tum musculo quam femina comparatur, secundum prevaletentiam sexus incalescentis.* And accordingly it ought to be baptized."

Such is the view taken by lawyers of the subject: but we see how far from being satisfactory it is; "according to the sexe that doth prevaile;"—why this is the very point at issue—it comprehends the whole matter of inquiry, leaving it abundantly open to the discussion of the medical jurist.

CONCEALED SEX.

I have given several instances, in the course of this lecture, of the sex being *mistaken*—particularly in the cases of Derrier, Marie-Marguerite, and others. I should leave the subject incomplete were I to omit noticing that there are instances also in which the medical jurist may have to consider the question of *concealed* sex. But a very few words will suffice for the purpose. There can be no difficulty when the examiner has a fair opportunity of making the requisite inspection. Almost all the extraordinary examples of concealed sex on record, have been cases in which a personal examination has been carefully avoided. The person named Lavinia Edwards, a man of abominable character, who, for some years, used to dress as a female, is said to have deceived

several who were in the habit of seeing him; nor was the real state of the case ascertained till after his death. At the coroner's inquest on the body (in January, 1833), some of the most revolting disclosures took place.

Some curious instances of female sailors—young women putting on male attire, going to sea, and remaining for months undiscovered by their messmates, have of late excited a good deal of public attention. There have been also some extraordinary cases of women-husbands. In Jan. 1829, there was an inquest held in one of the Borough hospitals, on a person of the name of James Allen, aged 42, a sawyer, who was killed by accident while at work. This person was a well-formed female, and had been married for twenty-one years. The wife gave evidence at the inquest; she was an industrious hard-working woman, deplored greatly the loss of her husband, and protested that she was not aware of his being of the same sex as herself—though she had her suspicions of his virility.

The Chevalier d'Eon was another remarkable example of concealed sex. He had changed from male to female; and from female to male attire, several times during his life, and maintained a high degree of respectability in both characters. Bets to a large amount were laid as to his real sex, and even lawsuits were instituted upon the issue. It was not till his death, which happened in 1810, at the age of 82, that the mystery was revealed: it was then ascertained that the Chevalier was really a man, and not distinguished by any hermaphroditical peculiarity. I have lately seen an excellent portrait of him in female attire; he had handsome features, and made a very good subject for the artist.

You will find in the *Tatler*, No. 226, a very amusing account of a *Doctor Young*, who practised physic about the beginning of the last century, in London. The Doctor was a woman who dressed as a man; was twice married and had children, himself and his wife being occasionally confined about the same time. The paper is attributed to Addison, and has all the air of being an authentic narrative.

But in all these instances there have been secrecy, and more or less of mystery. The first step of the medical jurist would, of course, be to remove obstructions to the right comprehending of the matter in question; and probably this is all that would be required. Should there be any ambiguity in the case, arising from sexual malformation, or mixture of the essential characters, it would then be necessary to apply the principles already laid down.

MEDICAL PROBLEMS.

By D. GRIFFIN, M.D.

HOW ARE WE TO DISTINGUISH SYMPTOMATIC FROM IDIOPATHIC INTERMITTENT?

[Concluded from p. 108.]

It seems evident, that nothing but a very clear understanding of the real nature of the affection, and that at an early period of the illness, would have saved the patient in the first of these cases. It may perhaps appear that at the time the abscess was first opened, the trephine ought to have been used, and a more free opening given to the matter; but, independent of objections on anatomical grounds, arising from a consideration of the parts among which the suppurating portion of the brain was situated, it must be remembered that the bone had become carious. The matter had worked its way through it, and on opening the abscess had flowed out freely with all the relief that could be expected from any operation.

In the third case, if the woman had been largely bled on the first moment of her applying at the dispensary, and other active measures adopted, the suppuration of the parts would perhaps have been prevented. When I saw her on her bed, and ascertained the real nature of the attack a few days afterwards, I believe that to a certain extent it had already taken place, and that all remedies were useless. My brother mentioned to me that he visited a boy similarly affected. He found him in a chair, hanging over the fire, with his head resting on his hand; he had a dull, depressed look; the iris was sluggish in its movements, and somewhat dilated, and he complained of dreadful headache, which had commenced by pain in the ear a few days before. He was immediately bled and leeches, got saline purgatives with tartarized antimony, and had his head shaved and blistered. He nevertheless went on from bad to worse, and died in eight or ten days, like the others, comatose and paralytic.

With regard to the diagnosis, as it refers to intermittents, more may generally be gained by taking notice who-

ther the symptoms correspond in every particular with the apparent disease, than by other means. Thus, for instance, if it is observed that the paroxysms are in any degree irregular, it will lead to suspicion, because the irregular and complicated intermittents are not so numerous as those in which the paroxysms return at regular periods. If there be, besides this, a fixed pain in any part of the head, with restlessness, want of sleep, complete loss of appetite, and constant whiteness of tongue, it becomes still more probable, however perfect the remissions, that the symptoms are dependent on disease within the head; and if with these circumstances there is observed such a state of countenance as we have described, the nature of the case can no longer admit of question.

There were two very remarkable circumstances in these cases; one of them I have partially alluded to, and the other I have until now omitted to notice. The first was the close resemblance the paroxysms which occurred in them bore to those of regular intermittent, and the second, their having been relieved by the bark and sulphate of quinine. With regard to the former of these circumstances, it is necessary to mention, that the paroxysms came on for some time in both of the cases with considerable regularity. There was also a great likeness in the circumstances of the paroxysm; each fit was not merely an attack of shivering rigor, such as occurs commonly as a symptom of the formation of matter in internal parts, and which goes off after a few minutes; each attack was begun by a long-continued and severe rigor, which was followed by a regular hot stage that lasted some time, and ended in profuse perspiration, bringing with it for the time all the relief that would have occurred in regular intermittent; and this is another circumstance in which the resemblance to these diseases was extremely striking. The intermission was usually as perfect as it would have been in any one of them. The face was pale, the pulse calm, the thirst gone. The patient complained but little, and the only point on which they seemed to differ was that the patients could get but little sleep, and that when once the rigors had completely set in, the appetite never returned in the intervals.

It appears difficult to account for this

great resemblance between two affections that are in other respects so dissimilar, but the difficulty will not perhaps continue, if we pay attention to the following circumstances:—

When the symptoms of diseases, which are very different in their nature, bear any resemblance to each other, it sometimes happens, from the great difference there is in the diseases which produce them, that the symptoms themselves are supposed to be also in their nature dissimilar. We are apt to associate them with the causes from which we think they arise, and to imagine a difference in the former, because there is one in the latter. This association, however, is very mischievous in medical practice, and we should ever be watchful not to be misled by it. In a science surrounded with so much obscurity as that of medicine, it ought to be our constant effort to form habits of analyzing the process by which we have arrived at the opinions we find ourselves to hold; to observe whether they are founded in reason or probability, and to be ever on our guard against that not unnatural, but most delusive principle of assimilation, which makes us jump at conclusions almost without our consciousness, and which, in circumstances like these especially, has a strong tendency to lead us astray. We ought, in short, always to take care to distinguish the symptoms which are the facts of the case from the causes of them, which are almost always matter of opinion that may be well or ill founded, and remember that the causes being unlike does not necessarily make the symptoms different. The contrary conclusion, if adopted, would tend to puzzle us in the commonest cases, and would make the consideration of all obscure ones exceedingly difficult; but more than all this, it is not borne out by facts. For independent of the proofs of this that might be drawn from a consideration of other affections, intermittent fever itself is seen in connexion with a variety of causes, and though the influence of marsh affluvia is perhaps the most frequent one, it often occurs in situations where the existence of this agent cannot even be suspected: they are said to be produced by sympathy and by contagion. "Two children," says Mr. John Hunter, "had an ague from worms, which was not in the least relieved by the bark, but by destroying

the worms they were cured." "We have in like manner," he says, "agues from many diseases of particular parts, more especially from the liver and spleen, and from an induration of the mesenteric glands." One of the continental writers gives an instance of an intermittent produced by repelled herpes, and another of one which was produced by suppressed lochia.

But these paroxysms are capable of being produced by other causes also. The application of caustic to strictures in the urethra, it is well known, has frequently brought them on, and in some cases even with the utmost severity. I remember Mr. Kirby's speaking of a case in which he made use of caustic, in which its application was followed by paroxysms so severe and intractable, that the patient lost his life by it. Mr. Kirby was never an advocate for the use of caustic in such cases afterwards, which, though from motives different from his, seems to have been since almost entirely abandoned.

Now since no difference can be shown in any thing but the cause of these paroxysms, it is perhaps too much to assume that they are of a different nature in all these distinct cases. Indeed, when we consider the number of agents which are capable of producing them, it is obvious that the immediate cause of these paroxysms lies not in any particular organic lesion, but has its origin in some disturbance of the nervous system, and in the nature of the laws which govern it both in health and disease. It seems probable, too, that the action of the (so-called) remote causes, consists in producing the peculiar state of that system which is always present with these paroxysms, and the existence of which is indicated by them; and that the paroxysms themselves have no more connexion with marsh miasmata, than they have with any of the other causes which occasionally give rise to them, or than any one symptom of any disease has with the remote cause which produced such disease. This conjecture as to the identity of the state which exists in diseases so very different in connexion with these paroxysms, seems to be confirmed by the fact of their having been benefited by the bark. The reason why the effect of the bark could not be permanent is evident.

We frequently see it mentioned in medical writings, that the shiverings

from internal suppuration have often been mistaken for those of intermittent fever, and treated accordingly; but surely it would have been more practical, as they are sometimes capable of imitating them so perfectly, to point out to us some means of making the distinction.

The suppression of the paroxysms in our two first cases, by quinine, while the disease which occasioned them went on to a termination uninfluenced by the remedy, shows that the paroxysm was merely a symptom, and not even an essential symptom of the disease; it is of consequence, then (and this conclusion may be regarded as of general application), in drawing inferences from the subdual of symptoms by any remedy, to consider whether such symptoms are essential or not, whether they are sympathetic affections which might exist without the local disease, or with a very dissimilar one, or whether they are necessary and inevitable attendants on it; which arise, and live and die with it. I remember a case in which a long-continued and obstinate pain in the head, after having been relieved by solution of arsenic, was followed by hemiplegia; another was related to me, in which, after violent hectic with harassing cough was allayed by quinine, an extensive tubercular cavity appeared in the lungs after death; and a third, in which a similar cough, after being perfectly appeased by quinine, henbane, and cicuta, was succeeded by hæmoptysis.

The great mistake we are apt to make about intermittent fever, is in the disposition to regard it as an idiopathic disease, rather than as a symptom; yet, as the former, we meet with it very seldom in ague districts, while, as the latter, it falls under our notice every day. It is met with in the form of hectic fever; it is met with from irritation in the urethra; it is met with in spinal irritation, in hysteria, and as an attendant upon abscesses in the viscera. *It is, in fact, symptomatic of various diseased conditions, and bears the same relation to idiopathic intermittent that symptomatic inflammatory fever does to the idiopathic continued fever.* The former may arise from local inflammation, from disordered bowels, from worms, from nervous irritation, &c. The latter is almost always produced by marsh miasma, or contagion.

In conclusion, I may remark that the diagnosis of diseased conditions of the system, indicated by paroxysms of intermittent fever, deserves more consideration than those who have not fallen upon such cases as I have related, are likely to bestow upon it. A close study of it, with all its doubts and difficulties, can alone prevent us from confounding a very treacherous and fatal disease with one that, in these countries at least, is seldom attended with danger. If the experienced practitioner gives himself the habit of regarding paroxysms of intermittent fever as a symptom sometimes indicating a state imminently hazardous to life, at other times by no means so, his first care will always be to observe what degree of evidence there is for the existence of the most dangerous state with which they are so often found connected. In this disposition of mind, he will seldom be inclined to overlook any means which the case may afford for obtaining an insight into its real nature, or to undervalue any testimony that may be present for the existence of the latter condition*.

* It is singular how protracted some of those cases of intermittent fever dependent on internal suppuration are. My brother tells me he was lately called to see a patient in consultation, who had been attacked with daily paroxysms of ague from a few days after her lying-in, which took place about three weeks before. The only circumstances in which it could be at all said to differ from regular quotidian, was, that the paroxysms sometimes, though rarely, occurred twice in the day. The patient had no apparent complaint with which the affection could be connected, when my brother saw her; but, from the sunk expression of countenance, the dull expression of eye, and excessive debility, he had little doubt that suppuration had taken place in some internal organ. There was no soreness of abdomen, no uneasiness in the hepatic region; there was no cough; the lungs sounded well; and the respiration was clear and natural when examined by the stethoscope. As he could not learn that there had been any symptoms of uterine or other local inflammation, and there appeared to be so much obscurity about the case, he recommended the continuance of the quinine, wine, and broth, which she had been already taking; believing, on the one hand, that there was a bare possibility of its being a case of idiopathic ague, and that at all events support was requisite; and, on the other, that if the affection was symptomatic of suppuration in some internal viscus, it would under any treatment prove fatal. The quinine suppressed the paroxysm once or twice for a day only, when it recurred again, and after lingering for a week or ten days longer, the woman died. On examination, about four ounces of matter were found effused in the cellular substance, which had formed a sac round it, close behind the right ovary, resting on the sacrum; the fallopian tubes at both that and the opposite side were full of pus, and there was about an ounce of it in the fundus of the uterus, which was all through lined with a black, gangrenous-looking slough. Here was a case of ague, undistinguishable from regular quotidian, continuing for a whole month, and yet occasioned by internal suppuration.—*Dubl. Journ. Med. Science.*

INDISCRIMINATE EMPLOYMENT OF ERGOT OF RYE.

To the Editor of the Medical Gazette.

SIR,

THE following case, shewing the ill effects of ergot of rye, has recently come under my notice. Perhaps it is of sufficient importance to be made public, as I am informed that the exhibition of the *secale cornutum* is very frequent with those practitioners who contract for parochial attendance.

In the year 1835, Mrs. —, aged 35 years, was taken in labour with her sixth child. A medical gentleman who attended the poor of the parish was sent for, but finding the case proceeding slowly, blamed them for sending for him so early. The pains were natural and regular. Notwithstanding this, he gave her the ergot of rye, which was followed by the most excruciating pains, one of them lasting for full two hours. Through the action of the drug, the head was expelled, and remained in that position an hour, or thereabouts. When the body was born, the foetus was dead; nor did the pains cease on the expulsion of the child; they continued, more or less, for four days. In consequence of such treatment, Mrs. — made her case known to a respectable inhabitant, who promised to assist her in obtaining my attendance on her then expected confinement.

Sept. 25th, 1836, at 4 o'clock, A. M., I was sent for, and found the liquor amnii had escaped, the head presented; the os uteri was not fully dilated. The pains regular, extending round her; these continued till 7 o'clock. Thinking they might last three or four hours longer, I returned home. At 8 o'clock I was again summoned; the pains had changed: the head had descended into the first outlet of the pelvis. I waited till half past 10 o'clock, the pains becoming very severe and powerful; nevertheless, the head remained fixed, or in a state of arrest. The os uteri was now fully dilated, and I determined on delivery with the forceps, which was accomplished, but not without great compression of the head, and much traction. As in the former instance, so in the latter, the foetus was of an unusually large size, certainly as large, if not larger, than any I had seen, after having practised midwifery

nearly 20 years. On inquiring of the mother whether she had suffered more this time than during her last labour, she stated that her present sufferings had not been half so severe as when she had taken the powder, or rather infusion. The mother and child are doing well.

The ergot of rye, though known as a therapeutic remedy in France as early as the beginning of the last century, has only of late years been brought into general use in this country. Nearly all the writers on its effects admit of irregularity as to its action. Dr. Blundell, in his lecture on Lingerin Labour, makes the following remark, which is worth attending to. "The secale cornutum is likely enough to destroy the foetus, if you use it—not in the lingering cases which we are now considering—but when the birth is delayed in consequence of increased resistance, rigidity, narrowing, or an unfavourable position of the head. In cases like these, if the secale cornutum be exhibited, and have a very lively effect, it may force the child down among the bones of the pelvis, where it may die by compression; not to mention that under the circumstances stated, there must be no small risk of rupturing the uterus."—I remain, sir,

Yours most respectfully,

JOHN GRANTHAM.

Crayford, Kent, Oct. 8, 1836.

BARON SLOET'S METHOD OF TREATING EPILEPSY.

To the Editor of the Medical Gazette.

SIR,

BARON A. SLOET VAN OLDRUITENBORGH, having communicated to me the remedy which he has employed against epilepsy, I wish to publish the prescription in your journal, in order that other individuals may have an opportunity of trying its efficacy; and more especially in consequence of the Baron himself being anxious to give it publicity. I am informed that the Baron's family have kept the prescription a secret for more than two centuries; and he states that he has given it during forty years to a great many epileptic persons, and that he has cured the greatest part of them. The particular ingredients are not unknown, and consist of

Pulv. Corticis Radicis Dictamni Albi
(Fraxinella), lb. j.; Pulv. Zedoariae,
3iss.

From this the patient is to take a powder of two scruples, more or less, according to the judgment of the physician, in aqua florum tiliae. He has increased the number of the powders to four in the day, but in those cases the zedoary has been reduced to one-half.

The Baron has also employed the dictamnus albus in the convulsions of children, with advantage. He recommends the dictamnus albus from Crete, in preference to that which grows in Italy, because the latter has no strength whatever; and he attributes the neglect of this remedy to persons having prescribed the pseudo-dictamnus instead of the real dictamnus.

The occasional employment of leeches ano, lavements, and aperients, are advised. I need not enumerate the different articles of diet which he prohibits, as it will be sufficient to state generally in a medical journal, that the patient should avoid whatever appears to interfere with the process of digestion.

I remain, sir,

Your obedient servant,

C. J. B. ALDIS, M.A. M.B.

The Hague, Oct. 14, 1836.

[A young officer was sent home from Bombay seven years ago labouring under epilepsy; the fits came on at least once in two months, and had endured several years: he consulted several of the most eminent practitioners in Edinburgh and London, without relief. He then went to Holland, and remained about four months under the care of Baron Sloet; from which time he never had any return of the fits, and has been able to continue his profession in India ever since. A relation of his under nearly similar circumstances, went in consequence to the Hague, and was also cured. In both instances the parties were bound by solemn promise not to reveal the nature of the remedy.—*ED. GAZ.*]

PUBLIC INSTRUCTION IN FRANCE.

[THE following document was drawn up by an intelligent English student in Paris, at the request of one of our most distinguished hospital surgeons here, by whom it has been forwarded to the *MEDICAL GAZETTE.*]

Every kind of instruction in France

is under the immediate superintendence of government.

One of the Ministers, named the "Ministre de l'Instruction Publique," takes the charge of all.

L'ensemble of these institutions bears the name of University.

No person can teach any of the different sciences or letters without having previously taken his degrees at the University.

The University is engaged in teaching Les Sciences Naturelles—Les Sciences Théologiques—Les Sciences Médicales—Legislation—and Les Belles-Lettres ;—from whence five grand divisions, known under the name of—

1. Faculté des Lettres.
2. Faculté de Droit.
3. Faculté de Théologie.
4. Faculté des Sciences Physiques.
5. Faculté de Médecine.

Medical instruction includes three large Facultés, each sharing equal rights in point of law ; but that of Paris is considered by far the best.

There is one Faculté at Paris, another at Montpellier, and a third at Strasbourg.

Almost every provincial town has a school, called *secondary*.

The secondary schools teach Anatomy, Surgery, and Medicine, and are only intended to instruct young men who aspire to become what are here termed *Officiers de Santé*.

Each Faculté is composed of a great number of professors, who teach the different branches of medicine.

All their lectures are public and gratuitous ; notwithstanding, in order to obtain the degree of M.D., young men are obliged to pay (under the name of "inscriptions") fifty francs every three months during four years, amounting to 800 francs, or 32*l*. Each pupil is compelled to undergo five examinations (during these four years), which are in the order as follow :

1st Examination — Sciences Accessoires*.

2d ditto—Anatomy and Physiology.

3d ditto—Pathology.

4th ditto—Legal Medicine and Midwifery.

5th ditto—All or every thing that concerns Medicine and Surgery, and more particularly Clinical Instruction at the bed-side of the patient.

And, lastly, each candidate for the degree of M.D. must compose a thesis, chosen by himself.

Each examination costs the candidate 50 francs, and the Thesis 50 francs more—total, 300 francs. Thus the whole amount of expense is 1100 francs, or 44*l*.

The Examiners are all Professors of the Faculté.

Each Professor has a fixed salary of 6000 francs, or 240*l*. per annum ; in addition to which they equally divide the perquisites of each examination, which amount to about 240*l*. more per annum.

All theoretical instruction is given in a most magnificent amphitheatre, where 1500 students can be admitted. Any individual may enter, on presenting a card from a physician or surgeon.

Practical instruction in surgery and medicine is delivered in the hospitals, where the physicians and surgeons devote daily two hours in the wards of the sick, and afterwards retire to the operating theatre, to deliver one hour's lecture on the most interesting cases in the different wards.

For the accessory sciences, chemistry in particular, pupils are admitted into the large laboratories at the *Ecole Pratique*, where every advantage is offered for manipulating.

Botany is taught in a splendid botanical garden belonging to the School of Medicine, admittance to which is always gratuitous and public.

Pathological anatomy is taught from amongst the numerous collections of the Faculté.

Practical anatomy is taught in beautiful, long, airy, and well-lighted rooms, (*Clamart*), where upwards of 2000 bodies are distributed annually for dissections and operations. Pupils can dissect during six months for 4*l*. Pupils may perform all the operations on the dead body twice over, and attend a course of lectures on surgery, for 25 francs (1*l*.), during the whole of the summer months.

Independent of this general instruction, to which all pupils are admitted, the School of Medicine provides or gives a special instruction to 120 young students, who are called "*étudiants de l'école pratique*." These students obtain this privilege by concours. All pupils are admitted. These students have the advantage of dissecting with much greater facility than other students ; their dissections cost nothing.

* Including Chemistry and Mathematics.

An institution exists in Paris, called "l'Administration générale des Hôpitaux," belonging altogether to the city of Paris; not under the control of "la Faculté de Médecine." This institution requires a certain number of young men to attend upon the patients of the different hospitals (they are what in England are called "dressers.") In return for their services they receive a moderate salary, and partial board and lodging; but are amply supplied with opportunities for distinguishing themselves in their profession. The salary is about 16*l.* per annum; in some 20*l.* For the "dresserships" of the different hospitals there are young men of two classes, known under the name of *externes*, 400 in number, and who are named by concours, 100 per year; their duty is to attend to the patients, dress them, &c. They receive no payment, but have the right "de concourir pour être internes."

Les internes, 80 in number, are obliged to follow the surgeons and physicians during their visits in the wards; to assist them in their operations; to inspect the faithful execution of the surgeon or physician's prescriptions; and, finally, in the absence of the surgeons, to direct whatever treatment they think most proper. If required, they may perform any operation in the absence of the surgeon: thus performing the duties of an assistant-surgeon in our English hospitals.

Independent of the instruction that the *internes* and *externes* possess, with reference to the treatment of diseases, "l'Administration générale des Hôpitaux," about four years ago, directed the construction of a most magnificent establishment (entirely and purposely for them), where anatomical instruction is afforded them decidedly with profusion. This establishment is called the Anatomical School of Clamart, where upwards of 2000 bodies are annually provided for them.

I have obtained information from the first authority on this subject in Paris, namely, the "Prosecteur" of all the Parisian hospitals, that no less than 5000 bodies are provided annually for dissection in the two anatomical schools of Clamart and the Ecole Pratique.

Organization of the Parisian Hospitals.

The hospitals belong to the city of

Paris. The inhabitants provide yearly a fund of 11,000,000 francs for their support.

There are upwards of twenty establishments appointed to receive sick persons, including hospitals for infirm, old, and mad persons. Each establishment is governed by a "Directeur," who receives a salary of from 3000 to 5000 francs per annum.

The "Directeur" of each hospital is obliged to give an account of his conduct to an "Administrateur générale," who receives a salary of 12,000 francs a year.

This "Administrateur," on the other hand, furnishes every necessary information of what passes in the different hospitals, expenses, &c. &c. to a "Conseil générale, formed of negotiants and respectable inhabitants of Paris.

This general Council is compelled to enregister its decisions by the Municipal Council; and, finally, the Minister of the Interior inspects these decisions.

The surgeons of the hospitals are nominated by concours. Every surgeon is admitted who has taken his degrees, whether at home or abroad.

The jury is composed of eight hospital surgeons; and the "Administrateur" presides also on the occasion.

The nomination of the successful candidate is confirmed by the "Minister de l'instruction publique," and the Council.

The professors of the Faculty are also elected by concours.

The jury is composed of two-thirds of the professors of the Faculty, and of one-third members of the "Académie de Médecine."

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

A Treatise on Tetanus; being the Essay for which the Jacksonian Prize for the Year 1834 was awarded by the Royal College of Surgeons, London. By THOMAS BLIZARD CURLING, Assistant-Surgeon to the London Hospital, and Lecturer on Morbid Anatomy. 1836.

To this Essay, as appears by the title, the Jacksonian Prize was awarded; and

from the research and discrimination which it displays, we have no doubt that the decision was a just one. On such a subject much of absolute novelty cannot reasonably be expected; and we look principally for proofs of the author having made himself master of all that has been recorded on the subject, and having drawn judicious inferences from the data thus collected. It is in this point of view that we think Mr. Curling's essay deserving of especial commendation: it displays great industry, and the industry of an intelligent mind; so that if the reader do not rise from its perusal with all the knowledge of tetanus which he could wish, at least he may be assured that he has had placed before him all that our imperfect art has yet made out regarding this obscure and intractable disease.

There do not appear to be any grounds on which a correct estimate can be founded as to the frequency of tetanus, as compared with other diseases, or of the proportion of cases in which it occurs after wounds — nor even of its average rate of mortality. It seems, however, to be well ascertained that it supervenes more frequently after wounds received in battle than in the injuries of civil life — probably from the subjects of the latter being less exposed subsequently. In a table given by Mr. Curling, and which contains the history of 128 cases, it is remarkable that in sixteen only did the disease occur in females; and that in these only four died, — being a mortality of but one-fourth; while of the remainder, amounting to 112 males, sixty-six perished, being more than one-half. The great majority died before the eighth day. One case is mentioned, on the authority of Wepfer, in which tetanus proved fatal in three minutes; and one by Professor Robinson, in which the patient was dead in a quarter of an hour. On the other hand, a case is related by Morgagni, in which death did not take place till more than three weeks from the onset of the tetanic symptoms. As to the interval between the receipt of the injury and the attack of tetanus, it is generally not less than one, nor more than two weeks; though instances are recorded in which three, four, and even more weeks have intervened.

The chapter on the Pathology of Tetanus is elaborate and interesting.

Many eminent continental writers, including Larrey, Recamier, Frank, and Brera, have maintained that inflammation of the brain or spinal cord is the cause of the disease. Now this doctrine is combated at considerable length, and, in our opinion, very satisfactorily, by Mr. Curling; who, without denying that inflammation is sometimes coincident with tetanus, yet holds and proves that this disease is frequently present where nothing whatever of inflammatory character is observed during life, or of the consequences of that action are to be detected after death. He also points out the distinction which it is essential we should make between pure tetanus and the spasmodic affections which accompany certain inflammations of the nervous centres — especially of the spinal marrow. In the advanced stage the distinction becomes easy, because paralysis usually takes the place of spasm, which is never the case in true tetanus.

The general result of our author's investigations leads him to infer that tetanus is a purely functional disease, the nature of which is hitherto undiscovered; that it is distinct from inflammation, and accompanied by no organic changes peculiar to itself; that the seat of the morbid action is the *tractus motorius*, the superior part being most frequently affected; that this tetanic irritation directly interferes with no organ except the muscular system, the other parts which suffer being implicated only in a secondary manner.

The *treatment* occupies many pages, but records little more than the results of unsuccessful experiment. Several well-authenticated cases are referred to, in which the patients recovered, although no remedies of any kind were adopted. In those where the patients recovered under particular methods of treatment, it is far from being always clear that the recovery was a *cure*.

As to local interference, the general evidence is against the removal of the injured part, even where this is practicable. Larrey is the chief authority in its favour, but the English army surgeons, by whom it was fairly tried, did not find it answer. Sir James M'Grigor, Dr. Hennen, and Mr. Guthrie, relate numerous instances in which it was adopted without the least advantage. The only modification of this treatment, which Mr. Curling regards as

deserving of farther trial, is the division of the nerves, where this can feasibly be done.

As to the general treatment, purgatives are recommended, so as thoroughly to clear the *primæ viæ*: a whole list of narcotics is disposed of in a sentence; and the accounts of mercury stated to be "far from favourable;"—in all which we cordially agree with the author.

In estimating the effects of blood-letting, it is of course important to attend to the distinction above mentioned, so that inflammation producing spasm may not be confounded with pure tetanus. In the former, venesection may be required, as in any other inflammations; but it appears from the table, that of twenty-six cases of tetanus in which bleeding was employed with other remedies, thirteen died,—giving us the usual average, and therefore affording no very encouraging prospect: at the same time we think Mr. Curling expresses himself too strongly when he says, "in the human subject I hold it to be dangerous in the highest degree." We believe, from what we have seen, that in some cases of pure tetanus, bleeding, if practised with discretion, is beneficial.

Probably more cases of tetanus have been treated by opium than any other remedy, and perhaps the greatest number of recoveries on record are where this medicine had been exhibited; but the circumstance above mentioned will prevent us from attributing too much importance to its influence. The quantity sometimes given will admit of no other explanation than that it remains inactive and unacted upon in the stomach. Thus Mr. Pereira, in his valuable lectures on *Materia Medica*, published in this journal, mentions an instance in which the immense quantity of four pounds, seven ounces, and six drachms of laudanum, together with six ounces, four drachms, and forty-five grains of solid opium, were administered within ten days!

Of all the remedies, however, employed against tetanus, tobacco is that which appears to us most deserving of further trial; and we are pleased to find our opinion corroborated by that of our author. It is very true that on turning to the table we find that out of nineteen patients to whom it was administered, only nine recovered; but the fact is, that in several, if not all the fatal cases, there were obvious circum-

stances to render the cause of failure apparent. Thus in one it was not adopted till the patient was *in articulo*; in two others it was barely tried, not being persevered in; in another there was organic disease of the brain; in one the remedy was carried too far, and the patient's death evidently hastened, if not actually caused, by its overwhelming effects. It is an agent of prodigious power, and must not be lightly meddled with; it ought, therefore, to be administered under the immediate superintendence of the medical practitioner.

Cold affusion is another powerful means of making an impression on the nervous system, and one which has repeatedly been eminently serviceable in tetanus; but, like tobacco, it requires discrimination, as patients have sometimes been killed by it. Thus Mr. Morgan relates an instance in which he directed a man with tetanus to be plunged into a cold bath; the symptoms disappeared on the instant, but he was taken out dead. This, however, was an extreme case, and is not to be taken as an illustration of what generally occurs. The best examples of success from the cold affusion are some in which wine was simultaneously administered rather freely. Dr. Currie's cases, in which four or five bottles of Madeira were drunk every day by the tetanic patient, are too well known to require notice. A case is given, which occurred in the London Hospital, in August, 1835, under the care of Mr. Scott, in which porter and ale were freely given, the latter to the extent of eight pints in the day; no intoxication was produced, and the patient recovered.

From the specimen of Mr. Curling which this volume affords, we can sincerely say we shall be glad to meet with him again.

MEDICAL GAZETTE.

Saturday, October 29, 1836.

"Licet omnibus, licet etiam mihi, dignitatem
Artis Medicæ tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

ROW AT APOTHECARIES' HALL.

SUCH is the title of a notice in the *Times* of Saturday; from which, and other sources of a private nature, we

learn that an affray took place on the 21st, being the last day appointed for the registration of pupils.

It has always been our effort to take as impartial a view as possible of the unfortunate differences which so frequently occur between the Worshipful Society and the medical students. We have never been led, like our contemporary, to hold that because the pupils were more numerous, and could purchase more copies of our journal, they must therefore be right in every thing they did; neither on the other have we been so wedded to the powers that be, as to think them infallible in all their proceedings. Between the contending parties (for such there is too much appearance of their being), we have endeavoured to hold the balance with a faithful hand—and so shall we now.

We do not think the young gentlemen who presented themselves to register their tickets were justified in any violent or riotous behaviour; but still less do we think the authorities at the Hall were warranted in adopting the course which is described in the *Times*. It is quite well known that the pupils—some from ignorance of its necessity, some from procrastination, and some from not having had the money sooner—postpone both taking out their tickets and having them registered till the last moment. This may be indiscreet, but such is the fact, and experience had shown the authorities at Blackfriars that it was so. Now we are given to understand, that this season, instead of any additional facility being afforded, the hours of registration were actually curtailed. But however this may be, it was quite apparent, before the 21st, that a large number of the pupils in London had not registered; and consequently, in our opinion, it would have been no more than proper to have made some arrangement to meet and obviate the inconvenience which must necessa-

rily arise. Nothing of this kind, however, appears to have been thought of; and accordingly, when the last day came, there was a rush of pupils to the Hall. The crowd was great, and the time short; many, therefore, began to fear that they would be excluded altogether, and hence we have no doubt that they became impatient. What was the consequence? Why, that beadles and constables, armed with sticks and staves, were called upon to restrain them; which they did by beating about their heads, and, if the report be true, felling several of them to the ground.

We take our information on this point from the *Times*. "The constables (we are told) were obliged to hammer their pericraniums with their staves," so that "a few of the young gentlemen had their polls brought into resounding collision with the pavement, and were much sobered thereby." Now, from the manner in which the Society of Apothecaries and their regulations have at different times been spoken of in that which is very justly called "the leading journal," we feel convinced that there is no hostile feeling toward them in that quarter, and consequently that there was no intention of bringing discredit upon them by this report. We trust, indeed, it would be doing injustice to any member of the court to suppose that the flippant paragraph to which we now allude emanated from one of them; but we are by no means so well satisfied that some of the subordinates did not resolve to take time by the forelock, and transmit to the newspapers such an account of this affair, with those whom they designate "hot-headed Esculapian tyros," as might have the appearance of the whole blame having rested with them, and that in fact they did require to have "their polls brought into collision with the pavement," before they could be sufficiently "sobered."

The only instance in which any thing

of a similar kind has ever occurred within our own recollection—we mean in which constables have been employed against any member of the profession in any of our public establishments—was when Leadbitter was called upon to thrust Mr. Wakley forth from the College of Surgeons: but here there was no “hammering of the pericranium,” nor any “collision with the pavement,” but the “hammering” was of quite another part, as it came into “collision” with each successive bench during his reluctant and somewhat undignified descent;—the *honourable* M. P. being merely dragged out by the heels in rather an unparliamentary fashion, and deposited with “gentle violence,” in the street.

Altogether, the present is a different affair, and we think some explanation is requisite. If true, it will be but an unsatisfactory piece of news for parents in the country, to read that some of their sons were beaten on the head by constables, when they went to register at the Hall. Again, if the account be exaggerated, it was the duty of the authorities whose conduct was thus impeached to see that a contradiction or explanation was immediately made public.

As it was, we perceive the registration could not be completed, and that the time was extended in consequence to the 26th. We trust that effectual means will be taken by the worshipful Court to prevent any risk of a like scene being again repeated.

A REVEREND HOMŒOPATHIST.

THE homœopathists continue to demonstrate their indifference to our criticisms—by almost daily letters in the newspapers. We have had *four* from Dr. Uwins; and, on his epistolography being exhausted, the pen has been taken up by the Rev. Thomas Everest, Rector of Wickwar. We regard these two antagonists with very different feelings. Dr. Uwins is merely weak—

Mr. Everest is ignorant, vituperative, and vain; pronouncing an opinion *ex cathedra* on the science of medicine, of which he evidently knows nothing, and most irreverently, if not profanely, dishonouring the Scriptures, by wresting them, on all occasions, to the purposes of angry controversy on matters wholly unconnected with the duties of his sacred calling. He formerly compared Hahnemann to our Saviour, and now likens himself and his inane efforts to propagate homœopathy to the mighty works of St. Paul, in support of Christianity! With an audacious disregard of truth, he represents the medical man who opposes the doctrines of the Germanic visionary as a “merchant of miseries,” whose only motive is the fear lest he should get fewer “of those rascal counters, with which agony fees his unwholesome palm,”!—and then, in a paroxysm of most unchristian zeal, exclaims—“*cleave the leprosy of Gehazi to him for ever!*”

We reprint his communication to the *Times*, and shall subjoin the passage in the GAZETTE which has called it forth, because even now that his letter of reclamation lies before us, we find it impossible to give any character of it more appropriate than that which was published by anticipation.

“When we inquire for their literature, we find their champion in the person of a worthy son of the church, whose talent for invective and the misapplication of texts of Scripture, forms his chief claim to public attention. We have had a specimen of him, and we can truly say we congratulate Hahnenannism on the possession of such a mild, meek, discreet, and sagacious partisan.”

To the Editor of the Times.

SIR,

IN a late number of your journal you inserted an article from the MEDICAL GAZETTE which contains a charge against me. It is with great reluctance that I reply to it; but now that I have

seen Dr. Uwins's letter, I think it right to make a few observations on the subject, convinced as I am that your gentlemanly feeling and sense of justice will not refuse to let him who has been attacked be heard in reply.

Touching the death of poor Malibran, as it is not my province, so it is not my intention to say anything. Any impartial person must come to the inevitable conclusion, that death under homœopathic treatment is very rare, judging from the delight with which the medical men have seized this opportunity to threaten Dr. Belluomini with the treadmill.

As to myself, in the first place I beg to tender my thanks to the Editor of the **MEDICAL GAZETTE**, for having exculpated Dr. Johnson from the charge of having written the article in question. Conceived as it is in the worst taste, it is quite refreshing to learn that Dr. Johnson is himself mistaken in asserting that he did write it.

In the next place, I would beg to assure that respectable editor, that his arguments against homœopathy are as devoid of novelty as they are of reasoning. There was one Demetrius, in olden times, who anticipated him. He collected the craftsmen, and to all Paul's arguments they gave no other answer than shouting together at the top of their voices, "Great is Diana of the Ephesians:" and when Paul argued, they put him in the stocks; when he entreated to be heard, they stopped his mouth by shutting him up in prison—a wonderful plan, doubtless, for deciding disputed questions; but it is singular that our worthy editor did not recollect that it was not successful.

I pity the editor of the **GAZETTE** much for the loss of his temper—more for the loss of his practice; but I see no necessity for his being vulgar. That the present absurd practice of physic is coming to an end, there is no doubt. Why cannot this editor adjust his robe round him, and fall gracefully, instead of spluttering like a cudgelled cockney?

He calls me (among others) a brazen impostor. I have no objection whatever to his using that or any other similar arguments against homœopathy, for I am conscious of its injustice. "Suffering is the badge of all my tribe." I pray to God that he will enable me to pass my very humble life in humble

efforts to do good to my species, even though "the Edomites and the Israelites, the Moabites and Hagarens, Gebal and Ammon and Amalek, cast their heads together" to abuse me for it.

I remain, sir,
Your very obedient servant,
THOMAS R. EVEREST.

Wickwar Rectory,
Oct. 17, 1886.

By the way, the term "brazen impostor" *was not* applied to the reverend gentleman, whom, till now, we have looked upon but as a wrong-headed fanatic; as, however, he takes the designation to himself as peculiarly his own, we beg to stand corrected, freely admitting that he must know his claim to it better than we can be supposed to do.

CHARING-CROSS HOSPITAL.

WE continue to receive statements and counterstatements about the recent proceedings at the Charing-Cross Hospital; but we cannot devote our pages to a discussion involving so much of individual misconduct, and so little of general interest. We may, however, observe, that the Committee have published what appears to us a complete refutation of certain charges brought against them by the medical officers whom they dismissed.

But this same document passes entirely *sub-silentio* that which impartial persons will consider as by far the gravest offence. It is this:—Report says, that in order to procure the recognition of the hospital by the College of Surgeons, the requisite number of individuals—namely, one hundred—were actually got into the house, and were seen by the deputation from Lincoln's-Inn fairly laid out and comfortably tucked up under the bed-clothes. But here the compliance with the conditions of the College seems to have ended: the number of patients straightway progressively diminishing, it is said, even down to sixty! Now this is either true

or false. If false, why has such an allegation been passed over, to refute others of comparatively little importance? If it be true, the deception practised involves the good faith of all the officers of the establishment; and the only prudent course is to avoid all discussion, so as to take the chance that in time it may be forgotten.

Meanwhile, we know that the hospital *was* in the list of the recognized, and *is* there no longer.

MEETING OF GENERAL PRACTITIONERS.

A LARGE body of gentlemen belonging to the Association of General Practitioners dined together on Thursday last, at the Bridge House Tavern. The card of invitation which they had the politeness to send us, owing to some mistake, did not reach us until too late to make any arrangement for being present. Under these circumstances we copy the following report from the *Times* of yesterday:—

“The dinner of the Association of the Medical General Practitioners took place yesterday at the Bridge House Tavern, on the Southwark side of London Bridge. The members, friends, and visitors of the Association, mustered to the number of 100 persons; and at six o'clock the dinner was served up. Mr. G. Webster was the chairman on the occasion. The *Non nobis* was sung, on the removal of the cloth, by Messrs. Broadhurst, Fitzwilliam, and other professional singers. After which, the chairman proposed the health of the King, the Queen, the Princess Victoria, and the rest of the Royal family, all which were drunk with the greatest loyalty and enthusiasm. The healths of the army and navy were then drunk, and the usual national songs sung on such occasions were given. On the toast of “success to the Association” which the company were assembled to commemorate, being proposed, the Chairman took occasion to advert to the state of the medical profession generally, and particularly to the situation of that portion of it which consisted of general practitioners. Certain persons had been pleased to call the general practitioners the subordinates of the medical profession. It was true the general practitioner did

not ride about the town in an elegant chariot, and pocket the guineas of his patients, nevertheless his labours were most useful, and it was necessary he should be a man of education and character. He (the Chairman) was glad to see assembled around him on the present occasion so many gentlemen of respectability in the profession. It augured well for the future benefit of the society, and it proved that that branch of the profession to which they belonged, and of which he also was a humble member, were at length resolved to exert themselves for the preservation of their rights. The medical profession of England was at the present moment in an anomalous situation. It was not only assailed without by the Eadies, the St. John Longs, and the Morisons, but it was in a degree distracted by the practices of those by whom it ought to be supported. In addition to the quackeries of other arts, homœopathy had been added to the list—a system of mysticism imported from Germany—a system founded on mystery. Mr. Webster then expatiated on the abuses arising from the manner in which the services of general practitioners were at present remunerated, and exhorted the company to use their exertions to bring about a better state of things. He hoped this meeting would form a nucleus, around which a much larger association would grow. The roots were already planted in the metropolis, and it would not be long before the whole country would be shadowed with the branches.

The health of ‘Dr. James Johnson, and success to the medical press,’ was then drunk with great applause.

Dr. J. Johnson returned thanks.

A great number of toasts more immediately connected with the medical profession were then drunk. An excellent song, written expressly for the occasion by Mr. Hudson, on the delusions of Homœopathy, was sung, and received *con amore* by all present, and the festivity of the evening was kept up till a late hour.”

DR. CHAMBERS.

THE Queen has been pleased to appoint Dr. W. F. Chambers to be one of her Majesty's Physicians in Ordinary. — *London Gazette*.

JARDIN DES PLANTES.

THE garden so called in Paris has been progressively increasing during the last forty years, and has now reached the extent of 84 acres. It contains 526,000 specimens of the three kingdoms of nature, among which are 10,000 different species of plants.

CLINICAL LECTURE,

Delivered at St. George's Hospital, Oct. 21, 1836,

BY DR. SEYMOUR.

*Rheumatism—Paralysis from Lead—Fungus
Hæmatodes of the Stomach—Epilepsy—Paraplegia.*

RHEUMATISM.

THE two cases of rheumatism of which I spoke in my last lecture, have proceeded quite satisfactorily, and the patients are nearly convalescent. The woman (Young) is, in point of fact, quite well; there is no symptom whatever remaining of the rheumatism. This has taken place in one week, so that no practice could be more efficient than the one which was adopted. The other case, which occurred in a woman named Jean Vaughan, and who was a great deal worse than Young, is likewise nearly convalescent: nothing remains but some slight pain about the shoulder and hips; the swelling and redness have entirely disappeared, and her hands, which were so much swollen as to prevent her using them without great distress, are likewise quite well. The only alteration in the mode of treatment was, that I was obliged to give her one or two doses of aperient medicine. I found that the guaiacum mixture did not act sufficiently on the bowels; it was omitted for a day or two; her bowels were then opened freely, after which we resumed the use of the mixture, and the issue has been such as I have stated.

PARALYSIS FROM LEAD.

The cases of poisoning from lead are essentially chronic in their nature, but those of which I spoke in my last lecture are better. Claney, who is suffering under disease of six years' standing, has less pain, and is taking nourishment. There is still necessity for continuing the daily exhibition of castor oil, to relieve the spasm of the muscles of the abdomen, under which he labours. The other is a case which will require weeks instead of days, before we can expect to see any decided alteration. However, the last report is, that the muscles of the abdomen have become relaxed; the appetite is improved, but the castor oil acts imperfectly; he was obliged to take several doses before we got any evacuation at all.

FUNGUS HÆMATODES OF THE STOMACH.

I now come to speak of a very important case, at present in the hospital—that of J. Wilson. Almost the first day of the session you saw in the dead-house the post-mortem examination of a man named

Hewitt, who laboured under fungoid disease of the stomach. A great many of you had an opportunity of seeing this man. He laboured under sickness, with occasional vomiting; great pain in the region of the stomach for a year and a half previously; and he came into the hospital in the last stage of the disease. When the body was opened, the whole of the pylorus was surrounded with fungus hæmatodes, deposited between the coats, so that the passage became compressed, and the passage of the ingesta was obstructed. The food was tolerably well digested, but it was accompanied with pain.

The present patient complains of pain in the abdomen, at a spot midway between the umbilicus and the ribs, on the left side. This is rather a remarkable position for the pyloric orifice of the stomach, but it is the less remarkable, because it not unfrequently occurs that this is the part referred to by the patient in such diseases. On making pressure externally, there is pain over an extent about the size of a small apple. This arises from the tumor growing externally, and pressing on the peritoneum and the parts adjacent. Internally on taking food, there is no pain and no vomiting. When you read in books of persons labouring under cancer of the stomach, the symptoms described are these:—As soon as the patient swallows food a burning sensation is felt, and soon after the food is returned, at first unaltered, but subsequently mixed with a bitter or sour fluid. After a time every thing taken is vomited, and then the patient brings up matter not only a little changed, but a quantity of matter resembling coffee-grounds. In this way the disease goes on, until death ensues. These are the symptoms named in books as the most important symptoms of cancer of the pylorus, but there is another disease which goes under that name, which is of a very different character, viz. the fungoid disease, of which I am now about to speak. Sometimes the internal membrane is not affected, but between the coats is deposited an enormous quantity of the same sort of matter which is found in the brain, the lungs, the liver, and the kidneys, and is termed fungus hæmatodes, or encephaloid disease. The present case is a very well-marked instance of the affection. Sometimes this fungoid matter exists in a very considerable quantity, and sometimes, as in the case before us, it is barely appreciable by the external touch. Some years ago I saw a gentleman who had been for years past losing flesh: though he had a very fair appetite, still his food did not seem to nourish him, but his general aspect indicated that he laboured under a malignant disease. Not being

able to detect any particular appearances, I requested him to lie in bed, that I might have an opportunity of examining his body. Midway between the umbilicus and the ribs of the left side was an enormous tumor, so large that I found he could scarcely have buttoned his breeches without perceiving it, and yet he had no vomiting, no pain in the part; his appetite was tolerably good, and never at any period during his illness did he reject his food. Here is a case, [presenting a specimen] where one half of the stomach is occupied by a fungoid growth, leaving the pylorus tolerably free. The specimen having been in spirits for a long time, has shrunk. Although the fungoid mass occupied so large a portion of the stomach, yet the patient went on to the last hour much as ordinary persons do, in respect to food.

How does it happen that in certain cases termed *cancer* there is pain and vomiting, while in other cases these symptoms are absent? In the great majority of instances there is a difference in the disease. In cancer of the stomach there is thickening and ulceration of the coats of that organ, whereas fungus hæmatodes is a new structure. In the latter case the tumor is very compressible, so that when food is taken into the stomach, it is pushed through the pylorus, the passage itself being left tolerably free. That is the case in the specimen on the table—the pylorus is not contracted. Here are some drawings by Cruveilhier, [exhibiting them] very beautifully executed, of true cancer. In such cases the patients become extraordinarily thin, and there is always pain and vomiting. Sometimes patients become so excessively thin, that you can feel the hardened portion through the abdominal parietes, but that is not commonly the case. Here is a case [referring to a drawing] where the lower half of the pylorus is scirrhus: it is like a case which I saw of Dr. Chambers's, in which the whole stomach was in this state. Here is a drawing of a case resembling as nearly as possible that of the patient up stairs: there is a fungoid growth, which may not be appreciable externally, but it surrounds the pylorus, and is deposited in the coats.

Another remarkable coincidence occurs: although there is no vomiting, there is another symptom — pyrosis, or water-brash. Where the growth is large, as in the specimen before you, the membrane secretes this water, and it is a symptom of the disease. In the present case there is no vomiting when food is taken into the stomach, nor is there any pain; but on pressing externally, pain is experienced, because pressure is made on the fungoid growth, and the peritonæum in the same

part intervenes; and there is also present this symptom of water-brash. I should beg you to observe, that although the water-brash may exist without organic disease, yet its presence is always suspicious, and it becomes essentially necessary to examine into the condition of the liver and the stomach. The water-brash consists in the bringing up, every now and then, of a small quantity of clear water. In a private case which I had under my care for two years, the only inconvenience which the patient suffered, was, that his mouth filled with cold water, so that he was obliged to leave the room and evacuate it several times in the day: the water was tasteless. In the present case, the patient represents the fluid as sometimes salt and sometimes bitter, and it comes up in small quantities. In many cases of this description this is a morbid symptom; but I do not mean to say that the moment you see it you are to conclude that the patient labours under cancer. I remember seeing the case of a patient, in Middlesex Hospital, who spat up a quart of water in a day, which had some acidity. When she died, it was found to arise from an enormous liver, in which there were tubercles of this fungoid disease. It is a symptom of disease of the stomach, or viscera; and where a person's looks indicate the existence of organic disease, it is to be looked upon with suspicion. It occurs in Scotland as a functional disease of the stomach, and is supposed to arise from eating vegetable food. How far that is true I cannot say; but in the present instance we look upon it as a symptom of deep-seated organic disease.

The practice in this case has been to place the patient on nourishing diet; and I will explain why I ordered the following medicine:—twenty drops of liq. potassæ; half a scruple of canella alba, and ten drachms of infus. cascarrilla. Looking at the case, in the first instance we should say that it was produced by inflammation, or increased action going on, and that stimulating remedies should be avoided; but in fungoid diseases we do not find that to be the case, and there is no medicine with which I am acquainted that will diminish the symptoms so much as this. I do not know that carminative medicines are attended with any other effect than the relief of the symptoms. Some patients will take brandy and water better than any thing else; and as it is a mortal disease, the patient should be made as comfortable as possible. Whether liq. potassæ acts on this as on tumors of a suspicious nature, it is impossible to say. I have seen patients take this remedy for many weeks, with an improvement of the general health, and certainly a delay of the

fatal symptoms; and this has induced me to give it in the present instance. If there had been a gnawing pain in the stomach, the medicine would have been ill applied, and I should have given something which would relieve that dreadful distress on taking food, which always occurs in true cancer of the stomach. The principal remedies to be looked to for the relief of pain are the absorbents, such as magnesia, or a saline draught. Ten grains of magnesia several times in the day will sometimes work wonders; or equal parts of magnesia and subnitrate of bismuth. In the case which you saw after death, the man was frequently relieved for many weeks by the subnitrate of bismuth, and was rendered a great deal more comfortable. I have seen this happen in many cases. The dose is ten grains of the subnitrate of bismuth and magnesia, and this may be given three or four times a day. It is not the magnesia alone which produces the good effect, for I have been obliged to have recourse to the bismuth where magnesia has failed; so that the bismuth has some specific action. Professor Odier, of Geneva, first employed it, and it became very popular in the north of Europe, especially in cases of cardialgia: the Emperor of Russia made him a present of a diamond ring. It was then used here, and not being found to answer in all cases, it seemed for some time to be laid aside; but the employment of it is again revived. It relieves pain, whether arising from functional or organic disease, and more especially where there is this secretion of mucus from the stomach, in a greater degree than any other remedy with which I am acquainted. The next best remedy for the relief of the pain is prussic acid; and I know that in the new Pharmacopœia we shall have a formula for its preparation. One of the evils attendant on this medicine is, that it decomposes very readily, and therefore we are uncertain as to its strength. In the usual form, two to three minims of Scheele's medicinal acid, at the utmost, exhibited several times a day, will relieve the pain.

In the present instance the object is, if possible, to diminish the growth of the tumor, to nourish the patient, and to give him those medicines which will cause a diminished secretion from the fungoid mass. With regard to the external pain on pressure, a blister has been applied, and ordered to be dressed with mercurial ointment, which is found the most effectual in these cases. The pain, however, arises from the external growth of the tumor and pressure upon the part, and not from the interior of the stomach.

A word with regard to the position in

which the tumor is found. You are aware that the pylorus is generally situated above the umbilicus, towards the right side, but here it is midway above the umbilicus, towards the left side. How comes it in this situation? The mass has increased in this direction, and become adherent. Sometimes I have seen it drag down two or three inches below the umbilicus; and in one instance it was so large and low, that it was believed to be a lodgment of feces in the colon, having caused adhesion. An opening was made (after consultation) by a very celebrated surgeon, and a small quantity of matter was let out, which appeared to have been contained in the tumor. Here [presenting it] is the preparation.

This is a very interesting case, and I recommend you to examine it; but I beg that you will not make hard pressure, on account of the pain to which it gives rise. Having seen one of these cases, you will never forget it. These tumors, which come in this particular part of the body, are very different from what, under cancerous disease, you would expect to be the case: this man may live for many years. The constitutional symptoms are extreme sensibility in every part of the body, and the pulse continues at about a hundred till the near approach of death. Sometimes a small quantity of fluid collects in the peritoneum, but not often. It not unfrequently happens that the veins absorb a certain portion of the mass; and it likewise not unfrequently occurs that the liver has a similar deposit in it of fungoid matter. I have nothing farther to say upon the case, than to advise you to watch it, because, although it is impossible to restore the man to health, yet it is interesting in a scientific point of view. To see the symptoms during life, and to be able to test them after death, is of great importance to men of our profession.

EPILEPSY.

There are three cases in the house, of the same disease (speaking from the external appearances), although they have probably arisen from very different causes. The first is the case of Gibbons, in Crale Ward; the second a boy, named Higgins, in Hope Ward; the third has only been under my care a few days, having come to me from the surgeons' ward.

Gibbons's case is perhaps the most remarkable. She is at present, to all appearance, in perfect health, and is about 24 or 25 years of age. About two years since, she was attacked with epileptic fits. Epilepsy is defined to be "convulsions, ending in sleep;" the patient falls down, and foams at the mouth. There are a

great number of symptoms which occur in particular persons. After remaining strongly convulsed and foaming at the mouth, for a period varying from five minutes to half an hour, the fit goes off, and the patient falls into a profound sleep. In the case of Gibbons the fits are very short, and she is attacked without any warning. In the great majority of instances the patient is warned by a sensation in the head, or a creeping sensation up the finger, or arising from the foot, or sometimes in the belly: and when it reaches the head, the patient falls down in a fit. This aura has been termed *aura-epileptica*. I do not think that it is present in any of these three cases. In a woman twenty-four years of age, suffering under such a slight form of the disease, we should naturally look to the uterine organs as the cause. There being no fall, no blow, nothing which could immediately call attention to disease of the brain, and there being no particular affection of that organ instanced by double vision or half vision, or palsy in any part of the body, the first thing in such a case is to inquire whether any part at a distance is suffering from deranged function; because (more particularly) the uterine organs being affected, parts situated at a distance sympathise with them. Thinking it very likely that this was the case here, I made inquiries as to the menstruation, and found that it was not very regular. As the fits were very slight, and were unaccompanied by warning, or by violent pain (for there was no pain, and no tangible symptom of organic disease), I endeavoured to treat it as an hysterical affection dependent on the condition of the uterus. She was consequently ordered to take large doses of *asa-fetida*, to be cupped on the sacrum immediately before the return of the period, and she afterwards used the cold shower-bath. There was some relief at first; the fits only occurred at the interval of a fortnight, and then again they became frequent. Subsequently to this she took *valerian*, but still without any good effect. Steel, in small doses, was tried, but it was obliged to be given up. She has been bled and cupped repeatedly for the complaint, without the smallest good effect. I held a consultation upon the case with Dr. Chambers, who recommended large doses of ammonia: it was tried, but without advantage. Sulphate of zinc was then used, but that also failed. Not finding that the ordinary remedies of a depleting, evacuating, or stimulating kind, were beneficial, I had recourse to what is sometimes very serviceable—rubbing the spine with a strong liniment (ext. bellad. in camph. lin.) This

is a great remedy with some persons, when hysteria goes to a great extent. As the woman has been here many weeks, no method has been left untried. Since I have resorted to this rubbing in, I think the fits have declined a little, and I wish it to be continued, to see whether those consequences will take place which I have sometimes heard of in private practice. These cases are all well worthy of your observation, because it is one of the most difficult diseases we have to treat; and if, on inquiry, you should find any mode of treatment followed by success, you will have numbers of instances in which to employ it in future life. These cases sometimes require to be very long under treatment, because there is a long interval between the fits.

The next case is that of Higgins, who labours under a very remarkable form of the disease. He was a cow-keeper, and he says that the man who was over him was very harsh, and beat him a good deal, but it does not appear that he beat him about the head. He is a great, thick, fat fellow, about twenty years of age, and of a plethoric habit of body. It is remarkable that the fits came on but once a month, and he says it is always at the full moon. The theory of the influence of the moon upon disease and mania, has long since been abandoned by all sensible men; but the only fits he has had have come on at the end of a month. I do not believe that the moon has any thing to do with them, but I do believe that there is, in a great number of cases, a periodicity. The disease first comes on at the end of a month, and then it does not occur again for a month; and when the habit is once acquired, there is often a periodicity observed. In certain maniacal cases, persons will be for a fortnight what is called *high*—difficult to manage; and then for a fortnight they will be *low*—that is, melancholy—and the change will take place at the same time to an hour; say at eleven o'clock at night. I knew one instance of a young lady who was deranged for many years, and was in these particular circumstances. She was in a house where the observations could be made with the most perfect accuracy. When I found her gay and lively, the nurse would say that she was within two days of becoming low; and to the day, almost to the hour, the change used to take place. There are circumstances which are observed likewise in nervous pain of the face: it will go on for three or four days, and then intermit. Intermittent pain of the head is very common, though it does not arise from marsh miasmata; and there may be an intermission of pain arising from organic

disease of the head. Where there is a regular intermission, arsenic will frequently remove it, even where it depends on organic disease.

This boy tried a great many things before he came into the house; and, among others, he had recourse to *charms*. Many of you have seen him; he is a good-natured-looking lad, with an abundance of red hair, and is rather a short fat person. Thirty unmarried ladies (for if there had been a married one it would have broken the spell) combined together to buy him a silver ring, to wear on his left hand, for the purpose of breaking off the fits. This, gentlemen, is "the march of intellect." He has desisted from the use of the ring, but with considerable difficulty. He asked one gentleman whether he did not think that there was something in it.

Charms have been from all eternity used for curing this disease, and often with effect, because the minds of individuals will sometimes exercise over these intermissions a considerable degree of influence. Epileptic persons who have warning of the attack, will sometimes be able to stop it. I remember a boy telling me that when the fit was coming on, he bit his tongue, and the pain kept off the fit. A ligature placed round the limb, or the putting on of a tourniquet, will sometimes stop the fit where there is warning. Undoubtedly there is no disease where charms have been so much resorted to as this complaint, more particularly because it has been supposed to be an infliction of Providence, and hence it has been called *morbus sacer*. The Druids allotted to it the mistletoe, the mistletoe being sacred to the gods, and therefore being the best to be employed in keeping off a divine infliction. Dr. Baillie states that he has seen epilepsy cured the most frequently by the nitrate of silver, then by *oleum succinum*, and thirdly, by the *viscus quercus*, or mistletoe; so that whether the Druids gave a good guess, or were informed that it would cure the disease, Dr. Baillie, a man of undoubted sagacity, had some confidence in this medicine.

On the 2d October this patient had a fit, and it recurred three times that day. When he first came in, I had him bled, and put him on antispasmodic medicines; his head was kept cool, and his bowels regularly purged. I believed that there was only some fulness of the vessels of the head; he was evidently fond of employing the functions of the stomach; and I thought by these means, and a low diet, I should keep off the fit. However, on the 2d October, the day that he expected the fit would appear, he had a severe attack, which lasted some considerable time, and

was accompanied by a violent pain in the head, by great stupor, and which left him very ill after it. He was again bled two days afterwards, but the blood was neither buffed nor cupped; there was no trace of inflammation, nor has been any whatever in the interval. Since that time there has been no fit, and he is, to all appearance, in perfect health. All that is done by me at present, is to keep him on low diet, to put him in the shower-bath, keep his head cool, and his bowels freely open. I believe that there is no evidence whatever of organic disease. If the periodicity of the disease should still continue, I shall be obliged to try him with arsenic in the interval of the fits, for the purpose of keeping off the intermission observed in the disease.

Of the last case, I can give you but little information at present: for the patient has only just been put under my care. He says that the disease arose subsequently to a fall, and if so, there is, in all probability, some organic disease in the brain. The case has been sent to me from Sir Benjamin Brodie, as not being a surgical case. I suppose, therefore, that there is some mistake in the man's statement, or Sir Benjamin's attention has not been drawn to the fall. The difficulty is increased by the man stuttering so as to make it impossible for him to convey an intelligible answer. I have desired that the history of the case may be obtained from his friends. He says that the disease is of about two years' duration; that it immediately succeeded the fall upon his head; and that he has had several fits a day, at intervals, since that time. We must endeavour to make out whether there is any injury of the brain, before we can proceed in the treatment with any hope of success.

Epilepsy may certainly arise spontaneously, without any organic disease. You are aware that the greatest people of antiquity were subject to this very complaint, and which, in some instances, was supposed to be a proof of increased, rather than of diminished, faculties. Julius Cæsar, every one believes to have been a man of superior talent, and yet he was subject to epileptic fits. Mahomet was subject to the same description of fits, and yet he was in possession of his faculties nearly to the last moment of his life—never, except during the fit, having shewn any thing but a knowledge of mankind, and their wants and wishes. A great many other persons have been subject to this particular complaint, without its shortening their lives, or impairing their reason; and consequently, it is certain that there are cases arising from functional derangement. Children are sometimes at

tacked with epilepsy from teething, or irritation in the bowels. Adults are liable to it—and particularly females, from a derangement of the uterine system. Still, however, there are a great number of cases in which epilepsy appears to depend on organic disease of the brain, and likewise where it ends in stupidity, fatuity, or madness. In all cases we must determine what is the condition of the brain. Where it arises in children from teething, and in certain cases even where it occurs at the period of menstruation, the cure is not very difficult; and there are cases in which the prognosis may be quite favourable. It will sometimes arise from the presence of worms. One of the worst cases that I ever witnessed—varying from epilepsy to catalepsy—occurred in a young lady affected with lumbrici; and yet lumbrici exist in many cases, without producing any obvious bad effect.

The treatment in the first case—that of the female—has been to endeavour to regulate, as far as possible, the uterine system, active remedies having been employed before. In the case of the boy, the object is to reduce the state of the plethora to the standard of health, and then to try to prevent the intermittent attacks from coming on regularly. And in the third case, we must ascertain whether there has been any blow which has caused organic disease of the head.

A great many observations have been made as to what part of the brain is most generally affected in epilepsy, and there are a number of disputes on the subject. Sometimes it has been thought that a small portion of bone deposited in the falx, and irritating the brain, has been the cause. I remember a case of this kind, which was discovered on opening the body after death, but where there was not more bone deposited in the falx than I have seen in many cases without such a result. Some persons have attributed it to bodies of the nature of hydatids, which are found in the plexus choroides; but in general, though not always, you will find the organic disease in the cerebellum. Some remarkable observations were made on the subject by two physicians in Germany—the Wenzels. They agreed, together with other medical men, to seek throughout the district round them for cases of epilepsy, to watch them, and when the patient died to examine the brain by the side of a healthy brain, so that they might more correctly see what was amiss. They published their work some years ago, in which I think thirty cases, with the post-mortem examinations, were mentioned; and in every one of these there was more or less disease of the cerebellum. There

is not the least ground for doubting the statements of these gentlemen; for either they were impostors, which we cannot believe, or the cases occurred. Assuming the latter to be correct, though it by no means proves that epilepsy, as an organic disease, may not arise from other parts besides the brain; yet it proves that it is very frequently, and most frequently, dependent on an organic alteration of that most important portion of the brain.

There is no evidence in any of the cases before us of organic disease, which is manifested in the interval, where that is the case, by other affections. If the patient see double, or half an object—if he remain after the fits in a state of stupor for a length of time, and the mind gradually declines, the fits becoming more frequent as he advances in life, we may believe that there is organic disease; and such cases, as far as I know, are absolutely incurable.

A great many counter-irritants have been recommended in this disease, one of which is tartar emetic ointment applied to the head, which will bring out pustules. Two drachms of tartar emetic may be combined with an ounce of hog's lard; and a bit about the size of a nutmeg may be rubbed over the head morning and evening. Some persons have great faith in this remedy. The late Dr. Jenner had a decided opinion in its favour, in cases of disordered intellect. He states that making an eruption at a distance is the way to cure the complaint. One of the causes alleged as productive of epilepsy all over the continent is the repercussion of a cutaneous eruption; and nothing is more common than to hear of the cessation of some eruptive disease preceding the epileptic attack. I presume that these were the cases in Dr. Jenner's mind when he recommended this medicine. He has published several cases of mania which were cured by this remedy. His work, which was published in 1822, is very difficult to be obtained. He shews that many diseases of the brain arise after persons have been accustomed to some habitual eruption, which has ceased. I saw the book fifteen or sixteen years back, but since that I was unable to obtain a copy. I tried the Medico-Chirurgical Society, the College of Physicians, and the British Museum, but it was not to be procured. I then wrote to Dr. Jenner's friend and executor, Dr. Baron, of Cheltenham, and he has let me see it. In the book are related, as I have said, many cases of tartar emetic ointment being rubbed on the skin having cured mania, the affection, in some instances, having supervened on the cessation of some habitual eruption. It was Dr. Jenner's practice to rub it on the

arms or legs: He recommends keeping up the eruption for the space of three weeks. I am inclined to think that, if in some of these cases I am not successful by other means, I shall give it a fair trial.

These cases, then, you will bear in mind. Read the symptoms as well as you can for yourselves, and observe the medicines prescribed, the object of which will be pointed out in future lectures, or at the bed-side of the patient. In this way you will get a complete history of the cases; and if you only discover what has had a great reputation, but will not cure the disease, even that will be a great matter.

PARAPLEGIA.

Before concluding I will call your attention to a case of paraplegia in Cambridge Ward, which I hope is going on well under the employment of tincture of cantharides. It is a curious and interesting case, and is worthy of your observation.

The patient labours under palsy of the hands and feet (diminished sensibility and motion), and some few weeks ago was totally unable to walk across the ward. There was pain of the head, and as it was not relieved by bleeding and every medicine which was administered, there was every reason to fear some organic disease of the brain. He took mercury, and subsequently strychnine, in such large doses, that I was afraid to give it any longer; and I then put him upon thirty drops of tincture of cantharides thrice daily. He is now able to walk with a stick, and feels his ankles and knees getting better. The only method of explaining the effect of the cantharides is by supposing that effusion goes on for a time in the brain and spinal marrow, and this is relieved by the diuretic effect, which is also the means of keeping down the effusion. Dr. Baillie has stated that in some cases paraplegia may be occasioned by these causes; and if the Doctor be right, there is a clue to the action of the tincture of cantharides, which does not produce any good effect, so far as I know, except where it acts as a diuretic.

The case has been a long time in the house, and I shall not enter into the whole of the history from the beginning; but since the patient has been put on this medicine the relief has been so great, that I should recommend you to watch the case for yourselves, as being one of those instances which, under ordinary circumstances, may be considered a great cure. Having adverted to some cases in which all our remedies fail, it is a comfort to find that the art of medicine has some resources in the most severe forms of disease.

TREATMENT OF FRACTURE BY A BONE-SETTER.

CORONER'S INQUEST.

THE most important inquest which has taken place in Lincoln for some years, was held at the County Hospital on Wednesday last, commencing at four o'clock in the afternoon, and continuing until ten at night. It was held before Mr. James Hitchins, coroner, and a highly respectable jury of sixteen citizens, on view of the body of John Scott, then lying dead in the hospital. — After viewing the body, the coroner addressed the jury, stating that in a town like Lincoln, it was impossible they could come to an inquest without receiving some intimation on the subject they were to decide upon, and he was aware there were various rumours afloat on the present occasion. He felt quite confident, on looking at the respectable jury assembled, he need not tell them they must be guided by the evidence alone, throwing all reports to the winds. After a few other observations the inquest proceeded.

William Bourn resided in Lincoln, and saw a man drive up to the Adam and Eve, in the parish of St. Margaret, on Thursday last, about half-past four in the afternoon; he was driving a three-horse van, belonging to Mr. Dawson, of Withcall, in which were eight rams. In attempting to pull up against the Adam and Eve, the van got master of the horses, which becoming unmanageable, threw over the vehicle, and pitched out both the man and the rams, just opposite the office of Frederick Burton, Esq., solicitor. The driver was thrown against the wall, but got up directly. Witness asked him why he drove so quick? to which he replied that his master ordered him to drive fast. He then said, "Oh dear, sir, my arm is broken." Witness recommended him to go to Mr. Mason, the bone-setter, which he did. Saw the deceased again at ten o'clock that night, at the Adam and Eve inn; he said he had got his arm set, and felt rather more easy; he had it in a sling, and had a bandage round his chest which confined his arm, and which *he stated was tight*. Did not see him again till he went to the hospital.

Thomas Hallofield, a stone-mason, residing in Eastgate, Lincoln, who saw the accident, corroborated the statement of the former witness, and added, that deceased got into his cart, at his invitation, and rode down as far as Mr. Mason's residence. Was at the Adam and Eve that night, when Mr. Mason came to visit him.

Mr. Samuel Hadwin, house-surgeon of the hospital, stated that on Friday morn-

ing, the 7th inst., about one o'clock, the deceased came to the hospital, having his right arm in a sling made with his handkerchief; there was another bandage round his elbow. Witness began to unwrap them. Deceased told him that the arm was very badly injured, and that Mr. Mason said the bones protruded. Hearing this, witness desisted, and had him conveyed into a ward of the hospital, where he was undressed and put to bed. He then began to unwrap his arm. Beneath the handkerchief which he removed, witness found a bandage which had been saturated with blood, but which was then dry and hard, and was bound several times round the elbow joint. Some portion of the bandage adhered so firmly, that it was necessary to cut it off. Immediately over the outer surface of the elbow joint, there was a large piece of leather, spread with some adhesive plaster, adhering very firmly to the skin, the removal of which caused great pain. At the back of the elbow joint, witness perceived a cut about an inch in extent, covered by lint. The neighbourhood of the joint was excessively swollen, and full of pain, extending into the elbow joint. The man's arm was placed in a convenient position on a pillow, and leeches and other applications were resorted to. After this he expressed himself relieved. Medicine was also administered. The deceased, when he first came into the hospital, stated that he was in very great pain.

Coroner.—From the examination of the arm, was the treatment which had been pursued, do you think, correct?

Witness.—It was diametrically opposite to what I should have adopted.

Witness continued.—Saw deceased again on the Friday evening, when he expressed himself more free from pain than he had been: the treatment which had been adopted was continued. On the next day, deceased stated that he had passed a tolerable night, and the distension above the elbow joint did not appear so great as before; leeches were applied, but the diminution was not striking. It was considered by the surgeon of the month (Mr. Hewson) necessary to bleed the man copiously: this was done, and medicines were administered, which had their expected effect, and he continued much the same until the evening.—On the following morning, witness found the deceased's arm, from the hand to the shoulder, very much distended: the remedies were continued. In the middle of the day the man complained of extreme pain in the arm; more leeches were applied, and the arm was steeped for a considerable time in warm water: from these means he derived great relief. In the evening, he complained of restlessness, and

appropriate remedies were administered. — On Monday morning, between seven and eight o'clock, deceased's arm was found to be in a state of mortification. At the direction of the surgeon for the month, a consultation was called of the surgeons to the establishment, who assembled at 10 o'clock. The patient was apprised of his danger, and that his death was inevitable, unless an operation was performed by the removal of the limb, and that even after that the chance of a favourable result was so trifling that they could hardly recommend it. This the surgeons themselves communicated to the poor man, but he decided to have the operation performed without delay. The arm was then removed at the shoulder joint. — Deceased's countenance after the operation was more favourable than before it, and he stated to witness that he felt more comfortable since the removal of his arm: he appeared to be in a much better state the whole of the day than any professional man acquainted with his previous state could have expected. On the following morning, unfavourable symptoms re-appeared; he then sank rapidly, and died at 4 o'clock in the afternoon, being sensible to the last.

Coroner.—There is one portion of your evidence, stating that the treatment which deceased received prior to his coming into the hospital was diametrically opposite to that which you would have pursued. What do you mean by that?

Witness.—It was decidedly opposed to all practice of surgeons, and to the first principles of surgery.

Coroner.—Is it your opinion that from the arm's being treated in the way you have described, mortification would be hastened?

Witness.—Decidedly. I should say, that if the party who bound up the arm wished to produce mortification, he took the very means he should have adopted for that purpose.

Coroner.—Was it possible for mortification to ensue from the wound itself?

Witness.—I think it possible that the injury itself might have produced mortification, even though it had been attended to by the surgeons of this institution; but the probabilities are that it would not.

Juror.—Do you think Mr. Mason treated this case as a fracture, or a wound?

Witness.—I do not know; his treatment is so much at variance with every principle of surgery.

Coroner.—By whom was the operation performed?

Witness.—By Mr. Hewson.

Coroner.—Was it performed in a skilful manner—as it ought to have taken place?

Witness.—Certainly: it was performed as skilfully as possible.

Coroner.—Was Mr. Hewson at all nervous?

Witness.—He was not.

Coroner.—My reason for asking that question is, because it is stated in the town that he was so nervous as to be obliged to call for assistance.

Witness.—I was at Mr. Hewson's elbow for the whole time, and there was not the slightest trepidation, nor did he ever require assistance.

Juror.—Did the patient die from the operation, or from mortification having entered into his frame?

Witness.—I am positive he died from mortification.

Mr. Hewson, Mr. Kent, Mr. Howett, and Mr. Franklyn, surgeons, were successively examined, as well as Mr. Mason. The jury ultimately returned a verdict of *accidental death*.—*Lincoln Mercury*.

CAMBERWELL PRACTITIONERS, AND THE MEDICAL CLUB SYSTEM.

To the Editor of the Medical Gazette.

“Candor dat viribus alas.”

SIR,

I WAS not Quixotic enough to wage war with a shadow, and therefore felt anxious that the writer who called himself a “Camberwell Practitioner” should come out of his hiding-place: and before I attempt to grapple with his arguments, I must be allowed to make a few observations with regard to the misstatements in both his letters. I again repeat that Messrs. Flower and Young are residing in the parish of Lambeth, and their paying for a Camberwell gas-light does not make them parishioners: it would be as fair to say that a man living in Holland Street must necessarily be a Dutchman!

What Mr. Flower means by “*gross abuse*,” I know not, but I assert that the language he describes was not used at the meeting alluded to; there was no “din and confusion;” the gentlemen who put their signature to the paper were not called “black sheep;” not a word was said about posting *their names*; and no individual was bold enough to offer to shed one single drop of blood in the cause: and will your readers believe it, sir, that, notwithstanding these assertions, Mr. Flower was not at the meeting; and as I have before said, though such a stickler for parishes and districts, is not himself living in the parish of Camberwell.

I will briefly recapitulate Mr. Flower's arguments in favour of this system, to

“avert the evil of such a measure” as the one produced by the Poor-Law Commissioners: these said Commissioners, however, are kind enough to recommend a remedy!—“*Timeo Danaos et dona ferentes*.”

1st. This system will improve the moral condition of the poor, and make them independent.

2d. It will prevent their having recourse to the parish-surgeon, through fear of a ruinous bill; and under this plan, they will have the option of selecting their own medical attendants.

3d. That it cannot degrade or injure our profession.

4th. That those who do the “work will have the pay,” and youths will not be sent to attend the poor women when in labour.

5th. That a dispensary is a far more objectionable establishment.

1. The very basis of the system is unstable and rotten, for it is founded in an *untruth*. The members of these clubs are told that they will become *independent*, when, in fact, they are in a state of *dependence*; but the great evil of the scheme is, that it holds up a bait for the upright man to leave the path of honesty and independence, and walk in that of pauperism. The dishonest man cannot be compelled to pay towards the club, and he will continue to cheat the members of our profession, many of whom are not (*considering the sphere in which they move*) so independent as the provident mechanic who receives 35s., or even 25s., per week.

2. Medical practitioners in this neighbourhood are not in the habit of sending *ruinous bills* to the poor; and I defy Mr. Flower to bring forward a single instance in Camberwell of a poor man who has been ruined in consequence of being compelled to pay a long bill! The poor will not be able to select their own medical attendants, as the majority of the medical men refuse to act.

3. Is it not degrading to a member of our profession to attend a mechanic earning 25s. per week for a less sum than the village farrier would expect for physicking his pig? And if this principle be once generally established, shall we not be injured by a *higher grade* adopting the same method for securing cheap medical attendance? When these clubs were first formed, those only were admitted as members whose wages did not exceed 10s. or 14s. per week, but now individuals subscribe who receive three times that amount; and is it not fair to suppose that the scale will gradually increase?

4. Here is the whole gist of the argument; for although *benevolence* is placed in the foreground, yet the “*non-remuneration*”

occupies the most prominent part of the picture.

With regard to youths being sent to cases of midwifery, I apprehend that those young gentlemen (who have attended lectures, &c.) are quite as competent to undertake the case as the parish midwife; and without this practice, let me ask, how are they to obtain that knowledge so necessary to make them efficient practitioners?

5. The same argument which Mr. F. applies to dispensaries is equally applicable to these clubs. "*Suo sibi gladio hunc jugulo.*" Many who now pay 3*l.* and 4*l.* yearly for medical attendance, and will not go to a dispensary, would, I believe, belong to this club. I contend that in London and its environs it is impossible to ascertain the amount of a man's wages; they may when he joins the club be 25*s.* per week, and the following month he may receive 40*s.*—although I admit that the plan may be practicable in a coal-mine.

The great cause of the misery amongst the lower orders of the metropolis does not originate in ruinous medical bills, but in the licensed "gin palaces"—

"Where sit, involved and lost in curling clouds
Of Indian fume, and guzzling deep, the boor,
The lackey, and the groom: the craftsman there
Takes a Lethæan leave of all his toil;
Smith, cobbler, joiner, he that plies the shears,
And he that kneads the dough; all loud alike,
All learned, and all drunk."

Leaving Mr. Flower to the enjoyment of his "homely and humble festal board of co-operation in a good cause," free from the "hollowest exultation," and graced with a "*mens conscia recti*,"

I remain, sir,

Yours respectfully,
E. CRISP.

Walworth, October 24, 1836.

P.S. I am living in Walworth, and practise in Camberwell; therefore I am a *Camberwell Practitioner*: and this will probably apply to all the gentlemen who were at the meeting (according to Mr. Flower's argument).

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

October 20th, 1836.

Edmund Thomas Halliday, Warminster, Wilts.
Alexander Paull, Truro, Cornwall.
Thomas Maitland, Tiverton, Devon.
Giles Symonds Roper, Mappercombe, Dorset.
Henry Rogers Burton, Market Harborough.
Richard Grimbly, Banbury, Oxfordshire.
William Derry Pearce, Launceston, Cornwall.
John Potter Sargeant, Leicester.
George Arthur Smith.
Frederick Walter.
George Wilson, Leeds.

Sackville Lupton, Thame, Oxon.
John Pechey, Isleham, Cambridgeshire.
Robert Druitt.
John Cartwright.
Edward Foot, Salisbury, Wilts.

NOTICES.

"R. H. B." will excuse us. His letter is an advertisement.

"MEDICUS."—We cannot take the same view of the conduct of the party aggrieved, as our correspondent does.

In compliance with the repeated application of several correspondents, we shall reprint in next number our abstract of Mr. Kiernan's Researches on the Structure of the Liver; the number in which it originally appeared having been long since out of print.

The papers of Dr. Ogston, Mr. Skey, Mr. Robson, Mr. Collier, Mr. Hunt, Mr. Thompson, "M. I.," and other correspondents, in our next.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE VI.

Other Medico-legal relations — Human and Comparative Structure — National peculiarities — Varieties of the Human Race — Form of the Head — Form of the Pelvis in different Nations — Family Varieties — Supernumerary Fingers and Toes. IDENTITY — Legal distinctions: 1. Identity of Living Persons — Family Likeness — Accidental Resemblances — Remarkable cases of controverted or mistaken Identity.

THERE are other relations, beside those of Age and Sex, in which individuals may be viewed and distinguished medico-legally. Some of these I shall introduce to your notice in the present lecture; others I am obliged altogether to omit.

Normal human structure.—The subject of disinterments alone suggests several inquiries which it would demand a certain degree of skill in human anatomy, and particularly in osteology, to satisfy. Without a competent knowledge of this kind, sutures might be taken for fractures, and fissures and foramina, for the effects of violence. For example, in a case cited by Dr. Paris, a man was accused of having murdered his step-daughter, by boring a hole in her skull with an awl. The body was exhumed after two years and a half sepulture, and an inquest held. Upon inspection of the head, a small hole was discovered near the ear, and the jury returned a verdict of wilful murder. It happened, however, that the circumstances of the case excited the attention of Mr. Sheldon. He obtained access to the

skull, and on viewing it, declared that the hole which was supposed to have been made with an awl, was only a natural opening, a foramen for the passage of a vein, and he pointed out the enamel-like structure of its sides, very different from the appearance of an aperture made by force. In confirmation of what he stated, he produced a dozen or more human skulls, having in them similar perforations, variously situated. The consequence was, that when the assizes took place, the grand jury ignored the bill.

Comparative structure.—Again, our skill in comparative osteology may be tested, where it may be necessary to distinguish the remains of a human subject from those of animals. Suppose only a few detached bones are found, we must show whether they be those of the human species, or belonging to brutes. The long bones of quadrupeds, and particularly the humerus, have sometimes confounded inexperienced observers. Strange mistakes, too, have happened among those who ought to have known better. The bones of elephants have been deliberately taken for those of giants; and it required the ability and authority of a Cuvier to prove that Scheuchzer's *Homo diluvii testis* was only in reality a gigantic salamander. But perhaps the most amusing blunder of the kind was that committed by the savans who examined the bones found in the grand sarcophagus of the second pyramid. Belzoni and others thought they had here the mortal relics of King Cephrenes: but Mr. Clift undeceived them; he showed that the precious remains were only those of an ox!

To attempt to lay down, however superficially, the principles by which you should be guided in investigations of this sort, would carry me far beyond the legitimate objects of my course. You must depend on your resources as human and comparative anatomists; and the more minutely and exactly you are acquainted with the details of both departments of knowledge,

the greater of course will be your advantages as medical jurists.

National peculiarities.—But there are certain other circumstances connected with the structure of the individual, which are both curious and legitimately within the province of legal medicine. I allude to national and family peculiarities of the human form.

Let us suppose a case—and experience has shewn that it is something more than ideal. A stranger from a foreign land presents himself, claiming to be considered as one in whom long absence from his native shores has operated great changes: his aspect is that of one of another race: doubts are entertained of his identity: and it is the interest of those who possess that property of which he may be the rightful owner, to be duly satisfied as to his pretensions. In such circumstances it may devolve on the medical jurist to determine whether certain physical appearances observed in his bodily structure, and supposed to be indicative of an alien origin, are congenital or have been acquired. Again, in cases of disinterment, when the remains must be identified, the deceased may have been a native of a distant clime; here it will be a part of your duty to note, among other points, the characteristic size, shape, and proportion of certain parts of the body. Should any of you practise in India, or in our distant settlements, it is by no means unlikely that you may be charged sometimes with such an inquiry as—whether, in a given case, the bones discovered are those of a European, a Negro, or a Hindoo?

It will be proper, therefore, to point out some of the principal differences of structure which characterize the

VARIETIES OF THE HUMAN RACE.

In the remarks which I have to make on this subject, I shall chiefly follow Cuvier, availing myself at the same time of the learned researches of Dr. Prichard.

Mankind is characterized by unity of species. By the term *species*, we imply separate and distinct origin, evinced by the constant transmission of certain peculiarities of organization. But there are *varieties* of mankind—understanding by that term certain diversities in individuals and their progeny, which are observed to take place within the limits of species. Different species, in fact, do not intermingle or propagate, while varieties may, and do.

Cuvier has adopted a threefold division of the varieties of the human species; Blumenbach a fivefold: while Prichard differs from both, in maintaining that there are seven distinct varieties. Fundamentally, I believe there is no material difference between these able authorities: they all seem to admit a threefold *primary*

division,—as nearly as possible agreeing with Cuvier's Caucasians, Mongolians, and Ethiopians.

Forms of the Head.

The sketches here before you will serve to give a good general idea of the form and proportions of the head, by which the three principal varieties are distinguished.

Professor Camper was the first who attempted to point out certain characteristic differences of the heads of men, and also of animals. His method was the well-known one of taking the facial angle—by imagining a line drawn from the meatus auditorius to the base of the nose, and another touching at once the prominent centre of the forehead, and the most projecting part of the upper jaw-bone—the head being viewed in profile. In the angle formed by these two lines he conceived to consist the distinctions not only between the skulls of the several species of animals, but also those which are found to exist between different nations.

Blumenbach, in the course of his long and constant study of skulls procured from all quarters of the globe, became convinced that Camper's method was very imperfect: he adopted, in consequence, another and more satisfactory mode of proceeding. His plan is to view the skull vertically, or with the vertex upwards, and then to observe its relative proportion of breadth. In comparing and arranging skulls, according to the varieties in their shape, we ought, he thinks, to survey them in that method which presents at one view the greatest number of characteristic peculiarities. "The best way of obtaining this end is to place a series of skulls with the cheek-bones in the same horizontal line, resting on the lower jaws; and then viewing them from behind, and fixing the eye on the vertex of each, to mark all the varieties in the shape of parts which contribute most to the national character, whether they consist in the direction of the maxillary and malar bones, in the breadth or narrowness of the oval figure presented by the vertex, or in the flattened or vaulted form of the frontal bone." This is called the *vertical* method.

Dr. Prichard, however, gives the preference to a mode of examining the skull first pointed out by Mr. Owen. It is the reverse of the vertical method: the skull is viewed from the base; and, as Dr. Prichard says, "the relative proportions and extent, and the peculiarities of formation of the different parts of the cranium, are more fully discerned by this mode of comparison, which has hitherto been much neglected, than by any other method."

But obviously we cannot do better than

avail ourselves of every possible view of the skull and its proportions—to survey it in all directions, as well laterally as vertically, and from the base. When this is

done, we shall be satisfied that all the varieties in the form of the human head may be referred, on a general comparison, to the three following classes.

FIG. 11.—*Head and Skulls of the Caucasian variety.*

1. *The Caucasian variety.*—This form of head is distinguished for its beauty, according to our European notions. It is that which characterizes the appearance of the Georgians and Circassians, in the neighbourhood of Caucasus, whence the human race is supposed to have so largely spread in the dominions of the world. It includes all the Europeans, with the exception of the Laplanders, the western Asiatics, and the northern Africans. The complexion is more or less white, the cheeks having a florid hue; the hair long, soft, and of a variety of tints—black, brown, chestnut, red, white, &c. The skull is of the symmetrical or oval form; the forehead is more

expanded than in the other varieties, “while the maxillary bones and the zygomatic arches,” says Dr. Prichard, “are so formed as to give the face an oval shape, nearly on a plane with the forehead and cheek-bones, and not projecting towards the lower part, as in other varieties of the human skull. The cheek-bones neither project outwards and laterally, nor forwards. The upper maxillary bone has the alveolar process well rounded, the anterior portion having a curve in a perpendicular direction. This gives a perpendicular and not a projecting position to the front teeth, to which the lower jaw and its teeth correspond.”

FIG. 12.—*Head and Skulls of the Mongolian variety.*

2. *The Mongolian variety* is characterized by the marked projection of the cheek-bones, the broad face, the small and oblique eyes, the straight black hair, the scanty beard, and the olive complexion. This race includes the eastern Asiatics, the Laplanders in Europe, and the Esquimaux in North America. The skull is of the broad square character: it is *pyramidal*, according to Dr. Prichard. “The cheek-bones,” says this author, in his excellent work on the Physical History of Mankind, “project from under the middle of the orbit, and turn backwards in a large arch or segment of a circle, the lateral projection of the zygomas being so con-

siderable, that if a line drawn from one to the other be taken as a base, this will form with the apex of the forehead a nearly triangular figure. The orbits are large and deep; the upper part of the face is remarkably plane and flat,—the nose being flat, and the nasal bones, as well as the spaces between the eyebrows, nearly on the same plane with the cheek bones.”

3. *The Ethiopian variety*, or that of the Negro, is remarkable for the blackness of the complexion, the woolly frizzly hair, the broad flat nose, the prominent muzzle, and the large lips by which it is characterized. The Africans to the south of the Atlas

FIG. 13.—Head and Skull of the Ethiopian or Negro variety.

chain belong to this variety. The skull is narrow and elongated; "the principal characters are referrible to the idea of lateral compression; the temporal muscles having a great extent, rising very high in the parietal bones, and being very large and powerful, subject the head to a force producing the effects of lateral compression and elongation. The cheek-bones project forward and not outward; the upper is lengthened and projects forward, giving to the alveolar ridge and to the teeth a similar projection. From the shape of the upper jaw alone would arise a diminution of the facial angle." This is the form of skull which Dr. Prichard terms *prognathous*, from the projection of the jaws.

Hardness and other peculiarities of the skull.—A striking character in the skull of the African Negro is its great hardness, density, and weight. It is frequently found to have a whiteness and compactness of texture, which give it the appearance of ivory or even of marble, rather than of bone. Nor is this condition of the cranium unaccompanied by a corresponding peculiarity in the skeleton generally. The bones of Negroes are usually much heavier than those of other men. The crania of Europeans differ greatly as to thickness and weight, those being usually found the heaviest which belonged to persons of diseased constitution. In the American nations, particularly those of the South, the skulls have been observed to be particularly light.

A remarkable fact respecting the Ethiopian skull has been observed by Mr. Owen; namely, the approximation made in its structure to that of the troglodyte. In several Negro skulls, and in one of an Australian savage, Mr. Owen noticed the juncture of the temporal and parietal bones, and consequently the complete separation of the sphenoid from the parietal, which in European and most African skulls meet for the space of nearly half an inch, a process of the sphenoid bone extending upwards to join the lower

anterior angle of the parietal. The same structure was observed in six out of seven young chimpanzees. But it is worth adding, that the orang resembles man in this particular: in seven out of eight crania of young orangs the sphenoid joined the parietal bone, as it commonly does in human skulls.

The Pelvis in different Races.

Some of the principal diversities of figure in the different races of men may now be briefly noticed; and first with regard to the pelvis,—for on the shape of this part the form of the body in great measure depends.

In the Negro.—The loins and hips are more slender in the Negro, and the pelvis narrower than in Europeans. The female negro, however, is supposed to have a very capacious pelvis,—though the evidence of that fact seems chiefly to rest on the circumstance that Negro women are said to have easy labours. Vrolik, who has bestowed much attention on the structure of the pelvis as indicative of national varieties, observes that the pelvis of the male Negro, in the strength and density of its substance, and of the bones which compose it, resembles the pelvis of a wild beast; while, on the contrary, the pelvis of the female in the same race combines lightness of substance, and delicacy of form and structure: nobody, in fact, on a first view, would suppose it to belong to the same nation as the corresponding part in the skeleton of the male. Yet the pelvis of the Negress has an elongated character, which likens it to that of the simiæ. The ossa ilii have a peculiar configuration. The summit of the inclined plane, which in the European is in the middle of the crest of the ilium, between the anterior and upper spine and the posterior and upper tuberosity, is situated in the Negress immediately above the posterior and upper tuberosity; being thus as remote as possible from its situation in the European. The anterior upper spines are placed lower in relation

to the cotyloid cavities, and are also less prominent. The anterior and lower spines are nearer to the edge of the cotyloid cavity than in the European pelvis, in which a greater distance is here to be observed. The length of the antero-posterior diameter, at the inlet, is great in comparison with the transverse.

In the Hottentot.—In the Bushman and Hottentot females, the breadth of the pelvis is about half an inch less than the pelvis of European women. The height is, on the contrary, much more considerable than in the latter; the ilia reach up beyond the level of the half of the fourth lumbar vertebra. The neck of the thigh-bone in the Bushman female is shorter than in Europeans, or even than in Negroes, and it has a more oblique direction.

In the Javanese.—M. Vrolik describes the pelvis of the Javanese as peculiarly light, small, and nearly circular in its upper cavity. He gives figures of this part in the male and female. From a first or hasty view of these, he says, any person would suppose himself examining the bones of a very young person, and nothing but the observation of those decisive characters indicative of full maturity would be capable of dissipating the impression. The muscles and their attachments are also inferior in every respect to those observed about the pelves of Negroes, Europeans, and Hottentots.

Professor Weber reduces all the various shaped pelves to four:

1. The *oval* form, where the antero-posterior diameter in the male is 3 in. 9 lines, and the transverse 4 in. 3 lines. This is the form of pelvis which is most frequently met with amongst Europeans.

2. The *round* form: this appears to be rather a modification of the oval, the conjugate diameter being somewhat longer than in the preceding form. It is said, however, to be the most frequent shape in the American nations.

3. The *square* form of pelvis—where the upper opening forms nearly a perfect square—the transverse diameter, however, somewhat longer than the conjugate; this is chiefly met with in people resembling the Mongolians.

4. The wedge-shaped or *oblong* pelvis, where there is an appearance of compression on both sides, so as to be narrower laterally than from front to rear. The conjugate diameter exceeds the transverse by some lines. It is said to be characteristic of the races of Africa.

It is right, however, to add, that Professor Weber is by no means so sanguine as M. Vrolik, as to the possibility of distinguishing varieties of the human species by the character of the pelvis. His deli-

berate opinion is, that every form of the pelvis which deviates from the ordinary type, in whatever race it may occur, finds its analogues in other races of mankind.

Other parts of the skeleton in different races.—There have been found six lumbar vertebræ in some Negro skeletons. But Dr. Prichard says he has seen the same variety in an European; and Mr. Owen has noticed an approximation to it in an Australian skeleton. The chest is often more arched and expanded in the Negro than the European. Soemmering notices a curious circumstance in connexion with this fact—namely, that in Negroes the eighth rib, or first false one, more nearly approaches the sternum than in Europeans: in one instance he found eight ribs attached to that bone. It is proper to mention that the same variety of structure has been met with in Europeans.

A certain peculiarity is said to have been observed in the fore-arm of the Negro, that part being longer, in proportion to the humerus and the stature, than in Europeans. But the authority for this fact is rather doubtful; nor is the difference of length, even on the shewing of the assertors, very considerable.

The Lascars and Indian sailors who visit England occasionally, are observed to have slender and elongated limbs. Length of the arms and legs, and smallness of the hands and feet, have been remarked as characteristic of the Hindoos. The natives of Van Diemen's Land, and of New Holland, are likewise small in stature, with long and slender legs.

The bones of the leg in Negroes, according to Soemmering, appear to be bent outwards, under the condyles of the femur, so that the knees stand further apart, and the feet are turned more outwards, than in Europeans. The observation is confirmed by Mr. Lawrence's account of the cast of a Negro in the museum of the College of Surgeons:—"The tibia and fibula are more convex in front than in Europeans. The calves of the legs are very high, so as to encroach upon the hams. The feet and hands, but particularly the former, are flat; the os calcis, instead of being arched, is continued nearly in a straight line with the other bones of the foot, which is remarkably broad." The foot of the black is commonly observed to be very large, and the hand to be remarkably thin; the fingers and toes at the same time possessing great flexibility.

Varieties of Structure affecting Families.

Peculiarities of structure which are hereditary in some families, are well deserving the attention of the medical jurist; they are excellent marks by which to determine the identity.

Among these, *supernumerary fingers and toes* are not unfrequently met with. Maupertius states that there were two families in Germany distinguished through several generations by six fingers on each hand, and the same number of toes on each foot. Jacob Ruhe, a surgeon, was one of this stock. His mother had married a man of the ordinary make, and bore him eight children, four of them partaking of her peculiarity. Ruhe transmitted his supernumerary members to his offspring.

Dr. Prichard cites from the *Edinburgh Medical and Surgical Journal* a very curious example of this peculiarity. In a family at Iver the individuals for nine generations had perfect thumbs, but instead of fingers had only the first phalanx of each, and the first and second joint of the ring finger of the left hand; these rudiments of fingers having no nails. It is added, that it was the women only who had the misfortune of entailing this defect

upon their offspring, which they did almost uniformly.

These must be considered as curious instances of variety of structure, not referrible to any original difference transmitted from first parents, but arising in breeds previously destitute of any such character; and when once arisen, becoming permanent in the stock. They serve to throw some light on the origin of the three varieties of the human race already described.

Sir Anthony Carlisle, in the *Philosophical Transactions* for 1814, gives an account of a family in which six fingers on each hand, and six toes on each foot, were transmitted through four generations. The originator of the peculiarity was a female of this conformation: she had ten children like herself, and an eleventh, who only differed from her in having one hand naturally formed.

FIG. 14.

Here is a representation of the feet of a young man who was not long since a patient of Mr. Arnott's in the Middlesex Hospital. He had seven toes on the left foot, and six on the right. Each of the toes had the proper number of phalanges, provided with distinct tendons. There were, however, but five metatarsal bones; two toes being articulated to the first metatarsal bone of each foot. In the left foot there were, besides, two toes articulated to the last metatarsal, as represented in the drawing:

The hands of this person were furnished originally with fourteen fingers, but two of them had been cut off from each hand in infancy. It is remarkable, that the patient had five brothers and four sisters, all of whom, with the exception of one sister,

had the sextuple peculiarity on their hands and feet; the said sister, however, having had seven toes on one foot, and six on the other. The peculiarity in this instance also seems to have descended by the female side.

IDENTITY.

We may now proceed to a subject more immediately practical—that of identity—in the discussion of which we shall see how the various peculiarities respecting Age, Sex, and the other relations already treated of, may be rendered available for the purposes of medico-legal research.

The aid of the medical jurist is sometimes required to elucidate difficulties arising from a confusion of persons, and in the absence of moral and

circumstantial evidence of a satisfactory nature, the proofs of identity shall rest altogether on the physiological facts which the medical man can supply. The determination of questions of this nature is generally fraught with public good, as it always is with interest for the public. It reveals impostors, or it enables the rightful owners of property to become the actual possessors: it rescues the innocent, while it brings his guilt home to the criminal.

The question of Identity may be raised either with reference to living parties, or to persons found dead. In coroners' inquests, the very first step of the proceedings consists in identifying the body, or such remains of it as are forthcoming. When the Dowager Marchioness of Salisbury was burnt to death lately, in the great fire at Hatfield-house, after digging for several days incessantly in the ruins, some of her remains were found; these were identified by the jaw-bone, in which were certain golden sockets for her artificial teeth.

Another legal arrangement connected with this subject is, that where a prisoner after conviction escapes and is re-taken, a jury shall be empanelled to try the collateral issue, namely, the *identity* of his person, and not whether he is guilty or innocent, for that is supposed to have been fully tried before.

I shall divide the subject of Identity as it relates to the living and to the dead.

Identity of Living Persons.

Family likeness is a thing of ordinary occurrence: the only wonder is that it is not oftener carried to such an extent as to confound identity. Instances, however, are occasionally met with in which brothers are so alike as to defy distinction. The following case, related by Risdon in his *History of Devon*, is worth quoting for its singularity:—

“Nicholas and Andrew Tremayne were twins, and younger sons of Thomas Tremayne, Esq. of Cullorcumbe, in this county. They were so like in all their lineaments, so equal in stature, so coloured in hair, and of such resemblance in face and gesture, that they could not be known the one from the other—no, not by their parents, brethren, or sisters, but privately by some secret mark, or openly by wearing some several coloured riband, or the like, which in sport they would sometimes change, to make trial of their friends' judgment, which would often occasion many mirthful mistakes. Yet somewhat more strange it was, that they agreed in mind and affection as much as in body; for what one loved the other desired; so, on the contrary, the loathing of the one was

the dislike of the other. Yea, such a consideration of inbred power and sympathy was in their natures, that if Nicholas was sick and grieved, Andrew felt the like pain, though they were far distant and remote from each other; this, too, without any intelligence given to either party. And what is farther observable, if Andrew was merry, Nicholas was so affected, although in different places, which they could not long endure to be, for they ever desired to eat, drink, sleep, and wake together. So they lived, and so they died. In the year 1564 they both served at Havre de Grace, where they differed, indeed, in outward circumstances, one being a captain of horse, the other a private soldier. Being both to the last degree brave, they put themselves into posts of greatest hazard. At length one of the brothers was slain, and the other instantly stepped into his place, and there in the midst of danger, no persuasion being able to remove him, he also was slain.”

But not only individuals of the same family, but persons no way related, have borne an extraordinary resemblance to each other. I shall not waste your time in recounting any of the old stories to be met with in books relative to this subject—many of them bordering on fable; but I may cite a few instances which have a more immediately medico-legal import. A gentleman of the name of Douglas had a narrow escape of being tried for his life some years ago, in consequence of the strong likeness he bore to Page the highwayman. He was committed to prison on the positive oath of a person whom Page had robbed.

Mr. Amos relates a remarkable case which occurred under his own observation at Warwick a few years ago. “A man was indicted for burglary, accompanied with great violence and cruelty, and the prisoner's person was identified by the woman whose house was robbed, and who described particularly the clothes he had on. Being told that the prisoner's life depended on the evidence she was giving as to his identity, the witness turned round towards the box, and having surveyed the prisoner very deliberately for some minutes, said ‘that is the man.’ On this one of the principal officers of the Birmingham police said, that he thought she was mistaken, and that she had been deceived by the appearance of another prisoner, who had had sentence of death passed on him the day before for another burglary, very like this in its circumstances, and that he was led to think so, as well from the strong resemblance between the two persons as from the circumstance that the dress the woman described was precisely the dress of the other man;

whereas the prisoner, who was a bad character, and had been for some time under the surveillance of the police, never wore such a dress. The other man was then produced in court, and the likeness appearing very remarkable, the jury acquitted the prisoner; though at one period of the trial nobody in court thought that there was the slightest chance of the prisoner escaping being executed*."

Cases are very numerous illustrative of the mode in which identity of the living has been contested and ascertained. One or two of these I may cite for you by way of example. The first is that of Baronet—a remarkable case from the *Causes célèbres*, frequently quoted, and which for that reason I shall despatch briefly.

Remi Baronet was born in the year 1717, in the diocese of Rheims. At the age of 25 he left his home to seek a livelihood, and it was not till twenty-two years afterwards that he returned to his native village to look after some little property which he had heard he was entitled to. In the meantime his sister, the widow Lamort, was in possession: she disputed the claim of the new comer—denied that he was her brother—and charged him with being an impostor. She went further. There was a man in the neighbourhood whose son was absent for many years. The woman Lamort, through the agency of her friend the Curé, succeeded in persuading this man that Baronet was his son, and he was induced to recognize the claimant. Babilot was the name of the old man who claimed Baronet for his son. In short, the widow conducted her plot so cleverly, that the unfortunate Baronet was condemned to the galleys for life, as an impostor.

On passing through Paris, on his way to the place of punishment, he was visited eagerly by the sister of the younger Babilot, the man who he was supposed to be. But the woman, the moment she saw him, denied that he was her brother: he was a much older man, she said; nor was he as tall as her brother, nor so well made. However, two years of the sentence expired in the labour of the galleys, when, at length, people began to think that it was possible the decision had been too hasty. An order for the revision of the sentence was procured, and the medico-legal investigation of the matter was committed to the celebrated Louis. He, upon examining the circumstances on all sides, found that there were five capital points of distinction between the two men. 1. Baronet—the rightful claimant—if he were forthcoming, should be 66 years old;

and the age of the convict appeared to amount to that number (here you will observe that the point of age was the first taken into account)—while Babilot should be no more than 46. 2. Babilot was a straight handsome man, and had been a soldier. Baronet was round-shouldered, and not much above five feet high. 3. It was known that Babilot had a *nævus maternus* on his thigh; this Baronet had not. 4. Baronet was lame, had clumsy feet, and large ankles; Babilot was just the reverse. And 5. Both Baronet and Babilot were known to have scars on their cheek and throat: but Baronet, in addition, had one on his eye-brow, which corresponded with the appearance of the convict.

The consequence of this well-conducted inquiry was, that an act was passed to reverse the sentence of the condemned claimant: the widow was deprived of the property, and Baronet was reinstated in all his rights as a good citizen.

The newspapers last year contained a short account of a case of mistaken identity, in some respects very like that just quoted. A man was hanged eight years ago, as Daniel Savage, the murderer of a female. The brother of the murdered woman was the only witness to identify the accused, and his evidence was vague. He had observed a cut on the cheek of the murderer, and there was found one on the chin of the prisoner. After sentence, up to the last moment, the convict persisted in declaring his innocence. It appears that the real name of this person was Edmund Pine—that he was subject to epileptic fits—and was of weak mind. When apprehended and examined before the magistrates, he was asked was he Daniel Savage; he answered "yes;" and gave the same answer to every question put to him. Furthermore (as in the *Baronet* case), the sister of the real Daniel Savage was admitted to see the prisoner, when in his cell under sentence of death; but on seeing him, she immediately exclaimed that that was not her brother.

A lamentable case of a similar description occurred in this country in the year 1749. One Richard Coleman was executed for a rape and murder committed on a woman named Ann Green. Coleman was convicted on the dying declarations of the prosecutrix; but his innocence was fully established two years after his execution, when another person was hanged for the same offence, upon the clearest evidence. The fatal mistake was obviously one of identity, such as persons are very liable to fall into when their senses are confused by bodily suffering, or the heat of passion.

Foderé relates a curious case, which

* MEDICAL GAZETTE, vol. viii. p. 36.

shows how cautious we ought to be in admitting even the evidence of eye-witnesses under certain circumstances. Two soldiers who were drunk got into a scuffle with some townspeople in the street: one of them presently left the ground, and his companion who remained happened to kill a man. Both soldiers were taken up, and a number of eye-witnesses designated as the murderer the man who withdrew. Justice was unable to come at the truth—yet the alleged murderer was condemned to be executed, and would have been so, had not the prisoners, in their respective hopes of obtaining mercy, where there was no striking a want of positive and consecutive evidence, confessed themselves which was the real criminal.

A CONCISE AND POPULAR VIEW
OF THE
MINUTE ANATOMY OF THE LIVER;
AS DESCRIBED BY
F. KIERNAN, ESQ. F.R.S.

(From his paper in the *Philosophical Transactions*, with the approbation of the Author*.)

WE have already laid before our readers Mr. Kiernan's elaborate and valuable paper, but we have received from so many correspondents applications for explanations of particular points, that we are quite satisfied some difficulty is found in fully understanding the author's views. We have endeavoured to give the chief points in a detached form, in such manner as we hope will render the importance of Mr. Kiernan's investigations more generally appreciated, still, however, referring to the paper itself, as contained at pages 324, &c. of vol. xv., for more complete and satisfactory details. We may add, that the present abstract has been seen by Mr. Kiernan, who has permitted us to express his approval of its accuracy.

SURFACES OF THE LIVER.—The liver has three surfaces—viz. 1st, the *external*, commonly so called; 2dly, the *canals* or *perforations* which contain the larger branches of the portal vein, hepatic artery, and hepatic duct, and called the

* And now reprinted at the request of several correspondents, who were unable to procure our abstract in a separate form, or without purchasing the volume (xv. *MED. GAZ.* 480) in which it originally appeared.—ED. GAZ.

portal surface; 3dly, the *canals* which contain the hepatic veins—the *hepatic-venous surface*.

SUBSTANCE OF THE LIVER.—This is made up of lobules, vessels, nerve, and cellular tissue prolonged from the capsule of Glisson.

LOBULES OF THE LIVER.—These are small bodies, based on certain branches of the hepatic vein, and bounded by a fine cellular expansion and plexus of vessels. The subdivisions of the hepatic vein are likened to the branches of a tree, and the lobules to leaves without foot-stalks resting upon them, as in fig. 1, which represents a magnified longitudinal section of a small hepatic

FIG. 1.

vein (*a a*), with lobules also divided longitudinally, and having a foliated appearance (*b b*).

The lobules are packed close together, but being of various shapes, and generally more or less rounded, they leave interstices between them, which are called the *interlobular spaces* (fig. 3, *b*), while the part where the flat surfaces appear to touch, are called the *interlobular fissures* (fig. 3, *c*). The lobules constitute the secreting portion of the viscus; each has its own system of vessels, and may be regarded as an independent gland.

VESSELS OF THE LIVER.—These are

the hepatic vein, the hepatic artery, and vena portæ; to which may be added the hepatic duct.

Hepatic Vein.—The larger branches of this within the liver are called *hepatic-venous trunks*; the smaller branches, on which the bases of the lobules rest,

centre. The branches of the vena portæ running between the lobules are called the *interlobular veins* (fig. 7, *b b b*). The minuter ramifications within the lobule are called *lobular venous plexuses* (fig. 7, *c c c*), and these last inosculate towards the centre with the *intralobular*

FIG. 3.

are called *sublobular veins*: each lobule, where it rests on the sublobular vein, is perforated by a minute ramule; and this little vessel, which occupies the centre of the lobule, is called the *intralobular vein* (see fig. 1, *e e*). When the lobule is cut across, this vein is seen to ramify from the centre towards the circumference (see fig. 2, *b, c*). The

FIG. 2.

intralobular vein of one lobule has no communication with that of another, but returns its blood exclusively into the sublobular vein.

Hepatic Artery.—This artery, which follows the ramifications of the portal vein and hepatic duct, is distributed exclusively on the vessels and other textures of the liver, for their nourishment. Its blood is then collected by minute veins, and carried into ramifications of the portal veins, where, being now venous blood, its farther course becomes the same as that of the vena portæ.

Portal Vein.—The ultimate destination of this is the spaces and fissures between the lobules, whence it is distributed to each particular lobule ramifying from the circumference towards the

FIG. 7.

centre. The branches of the hepatic vein (fig. 7, *d d*). The *interlobular veins* of one lobule communicate freely with those of the adjoining lobules (fig. 7, *a a*: three lobules are here represented). The larger branches of the portal vein are not in contact with the interlobular spaces on the surface of the portal canals, but are surrounded by a capsular investment, in common with the hepatic artery and duct. In such situations the three vessels just named send forth branches, which form plexuses in the sheath surrounding them; and these are called the *vaginal branches* and

FIG. 4.

plexuses. They in turn give origin to interlobular branches. The smaller portal branches are in contact with the interlobular spaces, except where the duct and artery (which always accompany them), interpose. From that part of the circumference of each vein which is in direct contact with the interlobular spaces, interlobular veins are given off *directly*, but at the other part vaginal branches first arise.—See fig. 4, which represents a transverse section of such a portal canal, containing the vein (*a*), the duct (*d*), and the artery (*e*). On one side the interlobular branches are seen arising from the vein directly (*b*), while on the other side vaginal branches are seen to arise (*c*), and afterwards to subdivide.

Hepatic Duct.—The lobular plexuses of the portal vein (see fig. 7) are accompanied by ducts, to carry away the bile

FIG. 6.

as it is secreted. These are seen with a microscope as minute yellow points when a lobule is cut across, and constitute the acini of Malpighi.—Fig. 6, *b b*, interlobular ducts; *d*, lobular biliary plexuses; *c*, intralobular or hepatic vein.

CAPSULE OF GLISSON.—This is a cellulo-vascular membrane, in which the vaginal, interlobular, and lobular branches of the portal vein, hepatic duct, and hepatic artery, divide and subdivide: it lines the portal canals, enters the interlobular fissures, and forms the capsules of the lobules; nay, it enters the lobules with the blood-vessels: and these several parts of the capsule are called *vaginal*, *interlobular*, and *lobular* portions respectively.

The portal canals, then, are occupied by the portal vein, hepatic artery, biliary duct, absorbents, nerves, and the capsule of Glisson. A general idea of the arrangement may be gathered from the

FIG. 5.

above cut, which represents a longitudinal section of a small portal vein:—*b*, the vein, which occupies by much the largest space; *g*, the duct; *h*, the artery—all of which are seen giving off vaginal branches; the fine tissue of the capsule investing the whole.

Sometimes one set of the vessels above described is in a state of congestion; sometimes another. When the *intra-lobular* veins are congested, the centre of each lobule appears of a more or less dark red, while the circumference is of a yellow colour: when the *interlobular* veins are congested, the circumference is dark and the centre lighter. The former is called *hepatic* venous congestion, the latter *portal* venous congestion. Both may exist together, and then the liver shews an uniformly dark colour. In *hepatic* venous congestion, which is by much the most common, the dark portions are detached; but in *portal* congestion they may be continuous. Considerable modifications take place in the aspect of the mottled appearance, according as one or other of these forms of congestion preponderates, and according as it is general or partial; but no such thing exists as the medullary, cortical, red, yellow, or other analogous substances, described by previous anatomists (by all of them, indeed, except Professor Muller, of Berlin), and on the supposed existence of which Andral has based his morbid anatomy of the liver.

STATISTICS OF SUICIDE IN
ABERDEEN.

By FRANCIS OGSTON, M.D., &c.
(For the Medical Gazette.)

IN Aberdeen, from 1826 to 1835 inclusive, the histories of fifty-two persons have been learned, who, in this period, have seriously attempted suicide: of these, thirty-eight have been actual suicides. Contrary to what might have been expected, the number of serious attempts was the same in females as in males. The fatal cases amongst the former amounted to sixteen, while, amongst the latter, we find twenty-two instances of the same. In men, we thus perceive that the actual were, to the attempted suicides, as 22 to 26, or as 1 to 1·18; in females, as 16 to 26, or as 1 to 1·62. Taking the returns of the census of 1830, as the mean of population during the ten years fixed upon (which gives the amount of the inhabitants of Aberdeen, including Old Machar, at 58,019), we have thus one attempt at suicide annually in every 11,157·5 inhabitants, including stran-

gers who had resided here for short periods. Calculating in the same way, there would be one actual suicide in every 15,268·15; a result which, compared with other places, cannot be considered otherwise than as very favourable for Aberdeen. But if we exclude strangers who have not had other than temporary residence, the result will be still more flattering; affording only one attempt at self-destruction annually, in every 14,168·29 of the fixed inhabitants, and one actual suicide yearly in every 20,006·55 of the same. As, however, instances occur which cannot be known, particularly in families amongst the better classes, the former calculation must be nearer the truth. We are not aware of any bills of mortality being kept in Aberdeen prior to 1833. In that year, an account of the deaths for eight months are in our possession. Taking the average of these, which gives one death in forty-seven inhabitants yearly, we have one actual suicide in 318·94 deaths.

We shall arrange the details which we have collected, connected with these cases, under different heads:—

1. Age and Sex.

The average age of 52 attempted suicides	36·19	years.
The ditto ditto of 26 male attempted ditto	41·15	—
The ditto ditto of 26 female ditto ditto	31·28	—
The ditto ditto of 22 male actual ditto	43·22	—
The ditto ditto of 16 female ditto ditto	34·25	—
The ditto ditto of 4 male incomplete ditto	29·75	—
The ditto ditto of 10 female ditto ditto	26·40	—

Or arranging them in quinquennial periods, we have—

Of Actual Suicide.

	Cases.	Males.	Females.
From 16 to 20 inclusive.....	2	1	1
— 21 to 25 ditto	7	3	4
— 26 to 30 ditto	7	3	4
— 31 to 35 ditto	3	1	2
— 36 to 40 ditto	4	3	1
— 41 to 45 ditto	2	1	1
— 46 to 50 ditto	3	2	1
— 51 to 55 ditto	3	3	0
— 56 to 60 ditto	4	2	2
— 61 to 65 ditto	1	1	0
— 66 to 70 ditto	2	2	0
— 16 to 70 ditto	38	22	16

The age at which the greatest number of attempts at self-immolation happens, is thus from 21 to 25 inclusive; next in frequency are the five years from 26 to 30. The periods at which the greatest proportion of actual suicides take place, are from 21 to 30 inclusive. Amongst the men, the greatest number

of attempts are from 26 to 30; amongst the women, from 21 to 25 inclusive. It is worthy of remark, that after the age of 35 (with one exception), no ineffectual attempt was made; and that a difference is observable in this respect between the sexes, fewer failures occurring in men than in women.

2. Mode of Death.—Attempted Suicide.

Total.....	38	22	16

From these tables we perceive that attempts to take life by fire-arms, and by cutting instruments, are confined, as might have been anticipated, to males, —poison and drowning being the modes most frequently chosen by the females.

The poison selected was laudanum, except in one case, where corrosive sublimate was swallowed. The throat was cut in five out of the six attempts by cutting instruments.

5. State—Married or Single.

Of the attempted suicides, 19 were married, 2 were widows, 1 was a widower, and 30 were single. Of the state of one of these last, there was doubts. Of these, 12 men were married, 1 was a widower, and 13 were unmarried. Of the women, 6 were married, 2 were widowers, and 18 were single. Or, the married (including widows and widowers) were to the unmarried as 22 to 30, or as 1 to 1.36. The married men (including the widower) and the single men were in equal numbers, while the married women (including the widows) were only to the unmarried females as 8 to 18, or as 1 to 2.25. Of the whole number of attempted suicides, it was known that 26 had no children, and that 16 had families. The average number of children amongst these, was 3 to each.

6. YEARS.

1. Attempted Suicides.

	Male.	Female.	Total Cases.
1826.....	1	3	4
1827.....	2	1	4
1828.....	3	2	5
1829.....	1	2	3

1835.....	3	2	5
From 1826 to } 1835 inclu- } sive.	22	16	38

The yearly average of the first table is 5.2; of the first five years of the same,

4.2; and of the last five years, 6.2; shewing thus an average of the attempts at self-destruction in this city.

The second table exhibits also an increase of actual suicides, the annual average for the 10 years being 3.8; the average yearly number for the first five years, 3; and of the last, 4.6.

7. MONTHS.

1. Attempted Suicides.

	Cases.		Cases.
January....	4	July	8
February ..	4	August	9
March	4	September..	2
April	2	October	6
May	1	November ..	2
June	6	December ..	4
	21	Total	52

2. Actual Suicides.

	Cases.		Cases.
January....	4	July	3
February ..	3	August	6
March	3	September..	1
April	2	October	6
May	1	November ..	2
June	4	December ..	3
	17	Total	38

From both tables, it will be seen that the last six months of the year predominate over the first, while August stands highest in each, and May lowest.

8. DAY OF THE WEEK.

1. Attempted Suicides.

	Cases.		Cases.
Sunday	8	Thursday ..	6
Monday	9	Friday	11
Tuesday....	7	Saturday ..	4
Wednesday	5	Unknown ..	2

2. Actual Suicides.

	Cases.		Cases.
Sunday	6	Thursday ..	4
Monday	8	Friday	6
Tuesday....	7	Saturday ..	4
Wednesday	2	Unknown ..	1

A reason may be assigned for Fridays standing so high in the first table. Tradesmen's wages are usually paid

here on the Thursday night, after which scenes of intemperance are very common. Many also receive their weekly pay on Saturday night, which is also often a period of drunkenness and riot, Sunday being occasionally spent in the same manner. Two of the week-day cases occurred on days of public worship, and must therefore be added to the religious festivals, in both tables.

The cases were arranged according to the days of the month in which suicides were attempted, or actually perpetrated; but no generalizations could be obtained from these, the instances being pretty equally divided amongst the different days.

It may deserve notice, that of 43 cases of attempted suicide, in which an approximation to the time was obtained, 29 took place in the hours from noon to midnight, and only 14 between midnight and noon. Of 32 cases of actual suicide, 20 were accomplished during the former, and only 12 during the latter twelve hours.

9. Religion.

Our information on this subject, and that which next follows, is less complete, and less to be trusted, than on the points which precede, and must therefore be received with caution. Of the 52 persons who attempted suicide, 14 attended no church; 13 frequented the Established Church; 2 the Methodist Chapel; 2 the Episcopalian Churches; and 1 the Relief. Of 20, nothing was known in this respect. On a very rough estimate (the respective numbers being unattainable at present with any thing like rigid accuracy), the attempts at self-immolation would be as 1 to 1384 of those attending the Established Church; as 1 to 900 Episcopalian; as 1 to 300 Methodists; as 1 to 1000 of the Relief Churches; and as 1 to 633 of those attending no church. This last calculation assumes, that one-half of those of whom no information was obtained attended no church.

10. Place of Nativity.

Of 41 attempted suicides, occurring amongst the resident population—

33 were natives of Aberdeen.

2 were from the south of Scotland.

2 were from the county of Aberdeen; and of 4 the native place was unknown.

Of the attempted suicides, occurring

amongst those who had no permanent residence in Aberdeen—

3 were from the south of Scotland.

2 were from the county of Aberdeen.

1 was a native of England.

1 was from Kincardineshire.

1 was a native of Elgin.

1 was from Morayshire; and of

2 the native place was unknown.

11. Habits.

Of the state of 30 out of the 52, whose situation was ascertained previous to the attempt, 20, or two-thirds, were intoxicated (1 from laudanum), and the remainder sober: 17 had the character of habitual drunkards, and an equal number of temperate persons.

12. Postmortem Appearances.

We had an opportunity of being present at eight of the postmortem examinations in the above cases of actual suicide. Independent of the morbid appearances peculiar to the mode of death, the following were observed:—

1. The skull in one instance was very thick, and nearly globular; in a second it was also very thick, but much flattened at the sides; while, in a third, it was very thin, with the processes and ridges on its interior unusually sharp and prominent.

2. Different morbid appearances were met with in the brain and membranes. In one case this viscus was very firm, and less dark-coloured than usual. In another instance the brain was very firm; in a third, soft, with bony concretions in each choroid plexus. In a fourth the arachnoid was thickened and opaque, and the cerebellum softened. In a fifth case serous cysts existed in each choroid plexus, while both thalami, one corpus striatum, and the septum lucidum, were broken down into a hard pulp. In a sixth the arachnoid was thickened, with effusion underneath, while the co-mutual surfaces of the hemispheres adhered; the brain generally being firm, but the fornix softened.

3. The following was the state of the heart in two cases:—In one the left ventricle was flaccid and attenuated; in the other it was loaded with fat, its right auricle and ventricle were attenuated, and its left ventricle hypertrophied.

4. In one case the lungs were emphysematous; and in another, generally

hepatized, with a bony concretion in the substance of one lobe.

5. In two cases the liver was hypertrophied; in one being of immense size. In a third the left lobe was softened.

6. In one case the stomach was contracted almost to the diameter of the duodenum.

7. In one instance the ileum was closely and permanently contracted; and in another the larger intestines were also unusually contracted, the mucous coat being in both instances softened.

8. In one case the os tincæ was found closed by glutinous matter; the uterus was as large as in the fifth month of pregnancy; its interior was filled with a downy vascular growth; the fallopian tubes were closed at each extremity, and distended in their middle by a serous fluid; both ovaria were the seats of serous cysts as large as a walnut. This occurred in a prostitute.

9. In one case the spleen was softened. One woman was deaf, and another blind.

In six cases the attempt noted was the second, and in one the third.

Aberdeen, Oct. 15, 1836.

ON THE
HYDRATED TRITOXIDE OF IRON
AS AN
ANTIDOTE TO ARSENIC.

To the Editor of the Medical Gazette.

SIR,
DR. BUNSEN'S discovery of the efficacy of the hydrated tritoxide of iron as an antidote to arsenic, seems to have received in this country scarcely the attention which its importance deserves. It is for the purpose of bringing it again before the profession that I send you the following narrative:—

On Wednesday, September 7th, 1836, a man bought a quarter of an ounce of arsenic, and about two o'clock in the afternoon mixed it in a teacup with a quantity of water, stirred it round two or three times rapidly with a teaspoon, and immediately swallowed it; a portion, not more than a quarter of the whole, remained at the bottom of the cup. He then walked out with a person who had unsuspectingly witnessed the proceeding, and who was quite incredulous till the man's altered countenance confirmed his positive as-

sertion that he had taken poison. Nearly a quarter of an hour elapsed before he began to feel sick; he then introduced his fingers into his throat to excite vomiting, and with some difficulty got up a mouthful of a clear fluid. Having reached a house in the neighbourhood, he complained of violent pain and retching; got some salt and water, which he immediately rejected with two or three pieces of potatoe, but the stomach still retained its other contents.

Mr. Sharp, Mr. William Furnival, and myself, saw him soon after three. He was sitting on a chair, with a wild and anxious expression of countenance, and his eyes were blood-shot; he was perfectly collected, and spoke correctly; had burning pain about his stomach and belly, which was swelled so as to have burst the buckle of his belt; violent beating at the heart, and an acid taste in his mouth.

A pint or two of warm water was thrown into the stomach by means of the pump, and on reversing the action of the instrument, a few ounces of fluid came back easily, but the tube became choked up, and was of necessity withdrawn. This was followed by a pretty copious rejection of fluid mixed with potatoes, pieces of which had got into the tube of the pump, and prevented its action. On being cleaned, it was again introduced, and another portion of warm water injected, but the pump, when reversed, still refused to act, and was finally withdrawn. The sickness had ceased, and could not be renewed by tickling the fauces. He felt something better after the vomiting.

It will not be thought irrelevant to say a few words on the state of the man at this moment. He had in the morning drunk a glass of rum and several glasses of ale. While under the influence of this liquor, and immediately before taking the arsenic, he had eaten five or six cold potatoes. The exact quantity of arsenic swallowed could not be ascertained, but it must have been a very large dose*. The vehicle in which he took it was one very likely to produce its peculiar effects upon the stomach; it was also evident that the sickness previous to the use of the pump had left the contents untouched, or

* A quarter of an ounce of arsenic sold in the shops equals two drachms and two scruples Apothecaries' weight.

nearly so. The injection of the warm water would still further dilute the fluids already in the stomach; and allowing that a portion of the arsenic was dissolved and vomited*, would not the very dilution facilitate the deposition of the remainder on the mucous membrane?

It was now two hours since the poison had been taken. About six drachms of the carbonate of iron were mixed in water and given to him at twice, one draught immediately following the other. He said his stomach felt cooler; and his pulse, which had been upwards of 130 just before, sank to 112. The pain ceased, or nearly so. He was ordered to bed, and to take half an ounce more of the carbonate in half an hour.

At half-past five I found him asleep, and in a copious perspiration. When he awoke he had no pain; there were occasional sensations of burning in the epigastrium, and strong palpitations; pulse 108; his eyes were still red, and his look anxious. A quantity of the newly-prepared oxide of iron was now administered. In the course of the evening he made a large quantity of clear and healthy urine. The pain continuing under the ensiform cartilage, he had ten leeches applied. He did not sleep. About two in the morning he was seized with violent pain and twisting in the belly, which was followed by vomiting; his bowels acted two hours after, and the urine was abundant. The matter vomited seemed to consist principally of the oxide, but at the bottom of the pot were some pieces of stringy mucus, which might be drawn up the sides amongst the urine; the stool could not be examined. He said he felt sick and worse after taking the physic; occasional heartburn; pulse 90.

On Thursday morning we had more of the prepared oxide, which was more carefully washed than the first. He said it was not so good to take; but he had no more sickness; pulse 75; slight headache. He slept soundly in the night, and early on Friday morning felt an inclination to go to stool, but passed nothing. The oxide was discontinued, and he had an ounce and a

half of castor oil, which operated twice. The first stool was of a formed consistence, of a dark green colour mixed with brown, and with several pieces of undigested potatoe in it, exactly like those vomited on Wednesday; the second stool was preceded by some griping, but was not seen. He had some twitching in his head on Saturday, so that, as he said, he was not able to hold it still. Had another stool, of a natural consistence, of a peculiar brown colour, and partially covered with a black shining mucus. His diet during the whole time consisted of gruel, tea, and dry toast.

The best commentary upon this case will be a detail of such experiments and trials as have been made with the oxide of iron since its discovery as an antidote to arsenic.

The history of the discovery is given in a letter from Dr. Bunsen to M. Poggendorf, dated May 1, 1834, which is published in the *Journal de Pharmacie* for October, 1834. "Having found, first, that pure hydrate of iron precipitates arsenious acid in solution so completely as not to leave a trace of it in the supernatant liquor,—and, secondly, that if a few drops of ammonia be added to the hydrate, and arsenious acid in fine powder be digested with it at a gentle heat, the latter immediately becomes an insoluble arsenite of the tritoxide of iron,"—the Doctor requested Dr. Berthold to experiment on some dogs, and the result was, that in their opinion it is a better antidote to arsenic than albumen is to corrosive sublimate.

Some months after this an accident occurred at Paris which led to much discussion and several series of experiments. Seven horses got some arseniate of potash in their corn; four died before any thing was done; to the other three M. Boulet, a veterinary surgeon, administered the hydrated tritoxide twenty-eight hours after the arseniate: one horse lived three hours, another thirty-six, and the other some days*.

These untoward circumstances gave rise to new investigations, and MM. Miquel and Soubeiran instituted a set of laborious experiments on dogs. After some preliminary trials, from which no

* A part of the fluid with potatoes rejected at this period, after having been boiled and filtered, was subjected to the action of sulphuretted hydrogen gas, and assumed the characteristic lemon tint, but remained perfectly clear.

* *Bulletin de Thérapeutique*, Oct. 1834. It is remarkable that in the first horse that died (of the seven) no arsenic was found either in the stomach or intestines.

positive conclusion could be drawn, they tied the œsophagus of a dog to ascertain how long he would live in such a state: the animal died in seventy-two hours. They next gave a dog twelve grains of arsenic, and then tied the œsophagus: he lived two hours. Another dog had nine grains of arsenic, and, with the same operation, lived two hours and a half. They now gave a small dog twelve grains of arsenic, and immediately after twelve times as much hydrated oxide of iron. The œsophagus was tied, and the animal left to itself; it tried to vomit. In two or three hours the effects of the poison went off. Twenty-four hours after the ligature was removed, and as the dog could not swallow solid food, some broth and milk was given to it. It died on the sixth day after the operation. In cases where the ligature was not removed, one dog lived seventy-eight, another eighty-four hours. It had the power of retarding death when given two hours after the operation; but when joined with fatty substances it was less efficacious.

After examining the chemical action of the two substances on each other, MM. Miquel and Soubeiran came to the following conclusions: — 1. That M. Bunsen's opinion, that the hydrated oxide of iron is a good antidote to arsenic, is correct. 2. The oxide must be used in excess with regard to the arsenic. 3. It instantaneously neutralizes and precipitates arsenious acid in solution. 4. When the powdered arsenious acid is added to the hydrated oxide diffused in water, its effects are completely neutralized by the oxide; but it recommences its action the moment the oxide is deficient. 5. The oxide will not prevent death when the poison has been long in the stomach. 6. While the oxide prevents any further action of the poison, it is not likely that it will do away the effects already produced*.

Early in March, 1836, M. Boulet, who has been already mentioned, read a paper to the Royal Academy of Medicine (of which he is a member), containing an account of additional trials. The subjects of his experiments were horses. The first got two ounces of ar-

seniate of potash, and immediately afterwards a pound and a half of the protoxide* of iron: the animal lived 57 hours. He now learned that similar experiments, with the same result, had been made at the Veterinary School at Alfort; and M. Lassaigne, one of the experimenters, accounted for their failure by the greater affinity between arsenic acid and potash, than between it and iron. In order to meet this, he tried the sulphate of iron. He gave two ounces of the arseniate, and directly afterwards a pound of the sulphate: the horse lived 63 hours. When M. Boulet mentioned these circumstances to Professor Orfila, the professor thought he had not given a sufficient quantity of the antidote; and in the next experiment he exhibited two ounces of the arseniate, and four pounds of the hydrated peroxide: death took place in 54 hours. A fourth horse had two ounces of the arseniate, and eight ounces of the sulphate of iron, and died in 52 hours.

In all these cases the usual effects of arsenic were found in the intestinal canal; and, moreover, in the two instances where sulphate of iron was administered, there was a serous infiltration between the mucous and muscular coats of the stomach. M. Boulet now gave up the arseniate of potash; and from six different trials found that it required two ounces of the white oxide of arsenic to kill a horse. On the 16th December he gave one, two ounces of arsenic, and immediately after it four pounds of the hydrated peroxide. The horse appeared quite well till the 25th, when he was killed: two ulcers were found in the stomach, one the size of a crown-piece, the other much less. In two other experiments the lesions were even lighter than these; in a fourth, the intestinal canal was found inflamed and swollen in different parts, and an erosion six inches long, and three broad, in the colon, penetrating through the mucous, and having disorganized the muscular coat.

To ascertain how long a time might intervene between the administration of the poison and the antidote, one horse had the former two hours, another four hours, before the latter. Both recovered.

* Bulletin général de Thérapeutique, Dec. 1834.

* It may be stated, that any difference of terminology in this article belongs to the original writers of the memoirs quoted.

In another case, the oxide given twenty-five hours after, at the time when the first symptoms of the poison appeared, produced no effect, and the animal died in twenty-four hours. M. Lassaigne analysed separately the contents of the stomach, the small intestines, the cæcum, and the colon, of a horse, which had been killed seventy-two hours after having taken the poison and the antidote, having shewn no symptom of being poisoned, and did not find a trace of arsenious acid any where.

As a summary, says M. Boulet, it seems to follow from these facts—1. That the hydrated peroxide of iron will not counteract the effects of the arseniate of potash. 2. That the sulphate is equally useless. 3. That it requires about two ounces of the arsenious acid to poison a horse, and death constantly follows on the second or third day. 4. That the hydrated peroxide of iron is an antidote to arsenic, and must be exhibited in a much larger dose than the poison. 5. That when it is given with the poison, it generally annuls the effects of the latter. 6. That it does so if given four hours after the poison. 7, and lastly, That it does not prevent death if given a long time after it*.

Drs. G. Borelli and C. Demaria, at Turin, were, about the same time, investigating the powers of the same substance, and published the results in the *Repertorio Medico-Chirurgico del Piemonte*, for March 1835: an abstract of their article is given in the *Bulletin de Thérapeutique* for May, to which I am indebted. Their first experiments were made on rabbits, and were unsatisfactory enough, till they ascertained that fifty grains of the peroxide alone was sufficient to cause the death of one of these animals in six hours. When they experimented on dogs, the consequences were different: in most of the cases the effects were as apparent as in those of Miquel and Soubeiran, and it would be a mere repetition to detail them. In one, six drachms of the tritoxide were given half an hour after fourteen grains of arsenic, and the dog got well; in another, after twelve grains of arsenic, five drachms of the tritoxide, which had been prepared fifteen days before, did not prevent the animal's death in twelve hours. Starch mixed with the tritoxide

retarded, but did not prevent its action. In no case was there any free arsenic discovered in the intestines.

These experiments, if not conclusive, were sufficiently satisfactory to induce any observer to try the peroxide in a case of poisoning by arsenic; and accordingly, M. Geoffroy, *officier de santé* in a provincial town in France, gave it to a man named Fouquet, a barber, who, in a fit of delirium tremens, had taken a drachm and a half of arsenic twenty minutes before. In the course of a quarter of an hour he drank five or six pints of hot or cold water, charged with the peroxide: this was followed by copious vomiting, and a large stool. Between six o'clock and two he was continually swallowing the same liquid, vomited thrice, and had as many stools. No symptom of the poison shewed itself, but he was still delirious. After eight hours the quantity of the antidote was gradually diminished, and the following morning (his senses returned gradually) he was convalescent, and asked for breakfast. This man took the oxide prepared from six ounces five drachms of the sulphate of the peroxide of iron, in from twenty to twenty-five pints of water, sometimes hot, sometimes cold*.

On the 13th of August, 1835, five little girls, on their way from school, picked up some pieces of a dry, brown, brittle cake, which had been thrown on a dunghill, and each partook of it, about two o'clock in the afternoon. In half an hour there was more or less vomiting, and the usual symptoms of arsenical poison, inflammatory and spasmodic. At five o'clock they got the tritoxide; the vomiting gradually ceased, the other symptoms subsided, and the next day the patients were all convalescent. The cake had been made two years before, for *rat poison*; and it was calculated that each had taken about thirty grains of the oxide of arsenic. These cases are detailed by M. Bineau, a physician, and M. Majesté, an apothecary, at Saumur†.

Two other cases belong to Dr. Buzorini, and are extracted from the *Medicinisches Correspondenz-Blatt*, in the *Gazette Médicale de Paris*, November

* *Bullet. de Thérap.* Mar. 1835.

* *Journal de Méd. et Chirurg. Pratiques*, Sept. 1835.

† *Journal des Connaissances Medico-Chirurgicales*, Nov. 1835.

1835. The poison was given in coffee, about nine o'clock in the morning, May 26th. Dr. Buzorini did not see the patients till six the following morning; one had suffered severely from ineffectual efforts to vomit; the other had been very sick. These and the other symptoms gradually gave way, and both patients recovered by the end of the month. The quantity of arsenic taken was, in one instance, not ascertained, but eighteen or twenty grains were found at the bottom of the cup; and, in the other, it is stated at thirty-five grains; but no data are given for this assertion.

Such are all the facts which I have been able to ascertain respecting this important discovery. It remains for me to describe the plan of administering the tritoxide in our case. The man, as has been stated, had six drachms of the common carbonate as soon as the stomach-pump was removed, and four drachms in half an hour more; this was done for the purpose of getting time to prepare the new oxide, after the formula used by M. Majesté, in one of the cases already mentioned.

Half an ounce of iron filings was put into an earthenware pipkin, and two ounces each of the muriatic and nitric acids poured upon them. This was put near the fire till the iron was dissolved; half a pint of distilled water was added, and in a few minutes the pipkin was removed from the fire, and an ounce and a half of liquid ammonia poured into it. A fresh addition of water was made, the whole stirred up, and allowed to settle for ten or fifteen minutes. The upper portion was poured off, and more water added, which, when the precipitate had pretty much fallen, was again decanted. The whole of this remainder was put into a bottle, and when we saw the man at half-past five, it was decanted into a basin to within three or four ounces, which formed the dose; and in this way he took half a tea-cupful of the dregs of the liquid every half hour. During Thursday he had it every hour. M. Majesté made use of twice the quantity of iron, &c., and states that from it he obtained twelve ounces of the hydrated tritoxide. M. Lassaigne prepared his tritoxide in the same way, but without the muriatic acid. MM. Miquel and Soubeiran make it with the sulphate of iron, a quantity of which is put into a capsule of platinum, or porcelain, with

five or six times its weight of water; when it boils, nitric acid is gradually added till the red fumes cease to appear. The liquor is then diluted, and the oxide precipitated by adding ammonia in excess: it requires washing like the other precipitates. It may be well to observe, that the precipitation takes place sooner in a large quantity of liquid than in a small one.—I am, sir,

Your obedient servant,

JOHN ROBSON,
House-Surgeon to the Warrington
Dispensary.

Warrington, Oct. 11, 1836.

ON THE NATURE AND TREATMENT OF ACUTE NEURALGIA, OR TIC DOULOUREUX.

To the Editor of the Medical Gazette.

SIR,

If you think the inclosed cases, with the accompanying remarks, of sufficient interest to warrant publication, you will oblige me by transferring them to your pages.

They relate to a disease interesting rather from its intensity, than either from its frequency or its danger, in the treatment of which, the medicine employed exhibited its remedial influence in so unequivocal a manner, that I make no apology for intruding them on the attention of your readers.

In the majority of cases of acute neuralgia, or tic douloureux, the pain has been referred to that part of the face involving the distribution of the 2d division of the 5th pair. Emerging as it were from the infra orbit. foram., the pain darts with electric rapidity towards its terminal ramifications, involving many, but limited in its greatest intensity to a few of its branches. When it has existed with severity during a long period, its frequent recurrence appears to involve the ramifications of the nerve which extend in the direction of the mastoid process. This may possibly have led to the belief that the portio dura itself might be the actual and primary seat of the disease—an occurrence which, if I may, without prejudice, determine from my own reasoning, and comparatively limited experience, appears to me, to say the least, highly improbable. My own experience has never furnished me with a case in which

the pain of acute neuralgia, arising in the neighbourhood of the stylo-mastoid foramen, extended itself along the track of the portio dura with the rapidity or the intensity with which it attacks the 5th pair. Doubtless, a certain amount of pain attends that frequent morbid condition of the portio dura which is the precursor and attendant on paralysis of the face: at least I have seen no example of the latter affection in which pain in that region has not been both a precursor and an attendant symptom. But in the latter description of case may not the nerve be secondarily affected, and is not the temporary suspension of its function referrible to the pressure of the surrounding parts, inasmuch as it invariably yields under the influence of local depletives and counter-irritants? If acute neuralgia consist in an inflammatory condition of an affected nerve, is it reasonable to expect that the ordinary signs of inflammation should be absent? Is it reasonable to attribute to the effects of inflammation, or to inflammation itself, a condition of nerve which admits of almost instantaneous mitigation from the use of remedies, highly aggravative of inflammation in other parts?

Do we possess any experience with which we can determine the amount of pain arising from actual inflammation of the portio dura, or even whether pain, unusual in kind or degree, would be an attendant symptom at all? The operation for the removal of a portion of nerve affected with acute neuralgia has detected no morbid, or at least no inflammatory condition of the nerve.

Again, it is notorious that a paroxysm of neuralgic pain is frequently induced by the most gentle application of the hand, by a current of cold air, or the slightest effort of the affected part; yet it will not only bear forcible pressure, but is actually relieved by it. If the pain be referrible to the distension of the neurilema, and their pressure on the nerve by the dilated vessels, of course the external pressure predominating, ought to increase the pain.

In severe cases of neuralgic pain of the sciatic nerve, the same fact, I believe, generally holds—pressure on the nerve for the most part mitigating rather than aggravating the pain. I have myself submitted cases of sciatica to the severest treatment, by cupping, blistering, and embrocating, from none of

which remedies have I ever obtained the smallest remission of pain. In one severe case thirty-six ounces of blood were taken at one time, by cupping over the track of the nerve. This was succeeded by a succession of blisters, liniments, and embrocations, without affording relief. Had the benefit been partial or temporary, a sceptical pathologist might have found material for an opinion favourable to inflammation; but the pain was literally unmitigated: and I speak with confidence on this head, for I was myself the subject of it.

Is there any difference, except in intensity, between the diseases known under the terms *tic douloureux*, neuralgia, and sciatica? They all affect sensitive nerves, the motor functions in the case of sciatica remaining unaffected; nor is this more remarkable than that the sensitive branches of the face can be paralysed, without the smallest influence being conveyed to the motor nerves of the same part. Neuralgia, either acute or chronic, is considered an excess of the natural function of the nerve, a “morbid sensibility;” and are not twitchings, chorea, or convulsions, a “morbid activity” of the spinal motor nerves in which sensibility is unaffected? Yet we do not treat these as inflammation of the nerves themselves, although they may possess a remote origin in altered structure. What are the most efficient remedies in neuralgia? Certainly not those which experience teaches us as most influential in the treatment of inflammation—ammonia, guaiacum, iron, colchicum, bark. A form of neuralgic pain which frequently attacks pregnant women, and occasionally referred to the presence of a carious tooth, I have repeatedly seen relieved in the course of a few hours by half-drachm doses of the muriate of ammonia, taken in solution. I cannot comprehend the nature of such influence on any theory of an inflammatory condition. Again: the treatment by depletion and counter-irritants, as far as I have seen, is invariably unsuccessful; nor do I believe that the digestive system exerts any beyond the most remote influence over the disease. To the above may be added, as unfavourable to the inflammatory condition, the fact of the periodical nature of the attacks in some individuals, with their pertinacious adherence to a few of the branches of the affected nerve; and this

is the more remarkable when we consider the propensity which the various forms of inflammation possess to extend along the textures primarily affected by them. Surely there is no resemblance between the influence possessed by the remedies employed in acute neuralgia and that exercised by bark, steel, and other tonics, in cases of chronic inflammation of the asthenic form, which, as it were, overwhelm the disease by the force and vigour they give to the circulation; for here the effect, though most imperfectly understood, is direct and almost immediate.

My friend and neighbour, Mr. Spry, a well-known member of our profession, has suffered from repeated attacks of acute neuralgia since the year 1827, which occupied the region of the lower jaw on the right side. The pain, which was occasionally intense, originated from the mental foramen of that side, and thence extended in various directions along the track of the mental nerve. When the attack was somewhat more than usually severe, the pain shot outwards towards the mastoid process, but never originated in that region. It was at any time excited by gentle friction of the hand, or by a current of cold air. Previous to the year 1835, he had employed most actively the remedies usually resorted to by professional men, with occasional, but only temporary, mitigation. During the early part of the year 1835, he consulted a medical gentleman of considerable experience in the treatment of similar affections, who recommended him that of counter-irritation. In consequence, he commenced the application of leeches, about a dozen at a time, which were repeated at intervals of two or three days. In this manner he applied, in succession, about six or seven dozen. This plan was prosecuted by the use of blisters, of which he applied many, and these were succeeded by an ointment composed of deuto-ioduret of mercury. The effect of these remedies, as regards the face, was great tenderness and excoriation, and a remitting pain was converted into an unremitting one; as regards the disease, it was undiminished. I saw him after this plan was relinquished, in a paroxysm of pain, and at my recommendation he took two scruple doses of the muriate of ammonia. The first dose relieved his pain in a very considerable degree; to use his own expression, "in a greater degree than any

medicine he had ever taken." The second dose produced a trifling diminution, while the third was inoperative.

About the month of August in that year he was recommended to try the effect of the aconitine, five grains of which, obtained at Morson's, in Southampton-Row, were rubbed down into an ointment with five drachms of cerate. The first application subdued the pain in a partial degree. It was applied in a small quantity by the forefinger over the track of the painful nerve, and was gently rubbed, or rather smeared, over the surface, for half a minute or longer. These applications were made according to the degree of pain—either once or twice in the day. They were applied during six days only, when the pain ceased entirely: nor has he suffered from relapse to the present hour—a period of fourteen months. He describes the medicine as very powerful, producing a sense of numbness over the jaw, which continued for about twelve or eighteen hours, and during which the functions of the motor nerve were perfectly unaffected—so that the effects were rapid and conclusive. He can now face any wind or temperature with impunity. He informed me that in consequence of the manifest advantages which he had derived from the aconitine, he recommended its use to a lady who, like himself, had been a very severe sufferer from this disease,—that she made the same applications, and with the same result, although she has, I am informed, suffered a slight relapse, from which the same remedy once more relieved her.

Richard Hodge, aged 40, a fisherman, of dark swarthy complexion, and apparently of healthy constitution, was admitted into St. Bartholomew's Hospital on September 10.

During the last eight years he has been suffering from acute neuralgia of the right side of the face, for the relief of which three molar teeth had been at various times extracted. On the extraction of the first tooth, a portion of alveolar process was fractured, by which the pain, instead of being relieved, was greatly aggravated. His medical adviser ordered him to be cupped, embrocated, and blistered, from which he derived no benefit. Among a large variety of other medicines which he had taken were dark powders (probably carb. ferri), which produced but little

relief, and, indeed, the whole treatment was inefficient. A surgeon at Scarborough, whither I presume he resorted for his health, extracted two sound teeth, and applied leeches and electricity during four months without benefit. From Scarborough he visited Exeter, where a repetition of the same treatment was threatened, but not carried into execution. During the whole of this period he had had no longer cessation of pain than three or four days in succession; and though he continued to follow his occupation of a fisherman, he was frequently driven on shore by the severity of the pain, for the occasional relief of which he resorted to laudanum.

His present symptoms are, severe darting and sometimes fixed aching pain, after long continuance, on the right side of the lower jaw, extending as high as about the middle of the face, and including half the nose; pain under the tongue; flashing of light before the right eye when the paroxysms are intense, causing depraved vision. He is rarely free from pain for more than two or three days, and describes a constant gnawing sensation over the affected side of the face; pain exasperated by movement in eating, drinking, or speaking, or by the application of either extreme of temperature: it often wakes him from sleep. Temperature of each side of the face the same.

His constitution is apparently healthy, and he has not been addicted to drink.

On the 14th I ordered him the ointment employed in the former cases—

Aconitin. gr. v.; Cerat, 3j.

Up to the 28th the ointment had been used most sedulously, without producing any perceptible effect either on the skin or upon the nerve.

On the 28th some aconitine, obtained from Morson, was used as above, the application of which was followed by the same benefit which attended its use in the former cases. When asked to describe the effect produced by the ointment, he said, "It appeared to search out the pain." He could not bear its use more than once a day, as his face swelled after its application. He likewise said it produced a numbness of his face for some time after. He applied the ointment about eight days, and from this period to the 11th of October he has had no recurrence of actual pain: on this day he left the

hospital in good health and spirits, suffering only occasional twitchings, which he declares "are not worth mentioning." He used ten grains of the drug.

These two cases are not introduced to your notice with the intent to claim the merit of originality of treatment;—I obtained the hint from others, and have but verified their recommendation. The interest of the cases may be found in the fact that an acro-narcotic poison will cure a local pain, where every description of depletive and counter-irritant has failed. What reasonable practitioner, however fond of trying new methods, would dream of rubbing in aconite ointment over a local inflammation?—yet why not, if tic douloureux be an inflammatory disease; for it will undoubtedly cure that. It appears to me just as reasonable to attempt the cure of local phlegmonous inflammation by aconite ointment, as to hope to mitigate acute neuralgia by leeches and blisters. Pain may be a concomitant of inflammation, but singly can never constitute it. When an attendant symptom, it never greatly preponderates, but always holds a certain ratio to the rest. And does not the very fact of excessive pain lead the practitioner towards the opinion, should inflammation really exist, that there is something more—some nervous derangement, either physical or vital, giving an eccentric character to the case?

Probably sciatica differs but in intensity from tic douloureux: there is the same irregularity of pain, darting along a sensitive nerve, and excited by the same causes. It will in some instances pursue with great exactness the distribution of the posterior crural nerve, dividing above the ham, and following the two branches of posterior and anterior tibial to the foot. Neither do these cases yield to counter-irritants or depletives, although sciatica runs its ordinary career more rapidly than the acute form of the disease. Its cure may be referred to means which really possess no influence over it. Sciatica, except in old persons and in confirmed cases, generally, I believe, yields to the influence of time without treatment, or at least is greatly mitigated by it.

During the last autumn, while I was on duty at St. Bartholomew's Hospital, I happened to have three cases of sciatica in the hospital at one time: one

case was complicated with other disease; in the other two, antiphlogistic treatment, as it is termed, had been freely but inefficiently applied by their respective medical attendants,—in one during six weeks, and in the other during three. Both recovered with comparative rapidity under the use of colchicum given in large doses, with guaiacum and opium.

The aconite, if a very expensive medicine, is at least a very powerful one. The drug first employed in the case of Richard Hodge was, I presume, obtained from a French house in London, by which it is imported from M. Pelle-tier in Paris. However, it was perfectly useless; while that which was obtained from Morson was as strikingly efficient.—I am, sir,

Your obedient servant,
F. C. SKEY.

Charter-house Square,

CASE OF POPLITEAL ANEURISM.

RAPID AND PERFECT CURE.

To the Editor of the Medical Gazette.

SIR,

SOME apology probably may be thought necessary for troubling your readers with an account of a case of popliteal aneurism; but I send the following as an instance of the shortness of time in which the circulation in the limb, and through an aneurismal tumor, may recur, after ligature of the femoral artery, in a subject, moreover, whose arterial system generally was in a morbid condition, and yet without impeding the perfect cure of the aneurism.

The number and size of the anastomosing vessels in the head and neck render the phenomenon of quickly-restored circulation less remarkable in cases where the carotid has been tied, of which fact numerous instances are on record; as one of which I may cite a case of orbital aneurism, of which a short report was given by me, and published in your journal for February 27th, where full pulsation returned in the tumor four hours after the operation, but yet without interruption to the entire removal of the aneurismal disease. The cause, however, of the

quick restoration of circulation in the present case is not so obvious, as the disease can hardly be supposed to have existed long enough, or to have attained sufficient size so far to interrupt the course of the blood through the main channel, as to give rise to much enlargement of the collateral vessels; and, on the other hand, the event proves there was no unusual division of the femoral artery, as occurred in a case operated on by Sir Charles Bell; and in one, a preparation of which is in the museum, I believe, of St. Bartholomew's Hospital: and these circumstances, of long-continued pressure from a large tumor, and unusual distribution of vessels, are the only causes commonly assigned as accounting for a rapid restoration of the circulation, as indicated by pulsation in the tumor, and continuation of the vessel below it.

Both the case above alluded to and the one I have now forwarded, show also the marked and the immediate good effects of blood-letting on the occasion of any considerable increase in the pulsation of an aneurism after ligature of the artery supplying it.

At the conclusion of the relation of the case of orbital aneurism, I stated that I should report any further change that might occur in the subject of it while under my charge. When he left the hospital his eye had quite returned into the orbit, and no vestige of the tumor remained, but with the paralysis of the left side of the face, including the eye-lids, unaltered; his vision, however, as far as the optic nerve was concerned, unimpaired.

In alluding to this case, I take the opportunity of recalling attention to two cases of aneurismal orbital tumors which were, I imagine, of a very similar nature to the one related by me, reported, the one by Mr. Travers, in the second volume of the Medico-Chirurgical Transactions, and the other by Mr. Dalrymple, in the sixth volume of the same publication. These two cases are given as, and I believe generally considered as, instances of Mr. John Bell's aneurism by anastomosis. The propriety, however, of this diagnosis may probably admit of question; but it would entail too long a disquisition to enter on the question here. I am not aware of other cases of similar nature being on record, nor, consequently, of any post-mortem examina-

tion which might throw positive light on the subject.

I have the honour to be, sir,
Your obedient servant,
JOHN BUSK.

Seamen's Hospital, Dreadnought,
Oct. 23, 1836.

P. R. Welshman, aged 37, admitted July 22d, 1836; short and muscular in appearance, but pale. He has a large pulsating tumor in the left ham, which protrudes also slightly on the inner side of the thigh, in front of the inner hamstring; painful on pressure, not discoloured, and compressible. A loud very distinct aneurismal whiz is heard on applying the stethoscope; pulsation in the tumor ceases on compressing the artery in the groin. It is stated to have commenced about five weeks ago, and no cause for it can be assigned, nor can he remember any sudden snap or attack of pain. The considerable size of the tumor prevents extension of the limb. Its greatest length is about five inches, and breadth about four. He states that he has long been subject to dyspnœa on exertion, and to sudden attacks of pain in the region of the heart. The heart's impulse is powerful, and can be felt over an extended surface; and with the stethoscope a strong bellows sound can be heard accompanying its action: this sound is loudest under the middle of the sternum, and on the left side, between the cartilages of the third and fourth ribs. The course of the abdominal aorta can readily be traced by the eye when he lies on his back, but is unaccompanied with any sound. The femoral arteries on both sides can also be seen to pulsate to their passage through the adductors, and they seem to the touch to be of larger calibre than usual. The continuation of the right anterior tibial on the dorsum of the foot can also be readily seen, but is not so distinct on the left. All the arteries which can be felt pulsate powerfully, and appear of large size, and the pulsation in most of them is accompanied with a peculiar sort of thrill.

In the evening he was seized with acute pain in the cardiac region, for which a sinapism was applied.

July 23d.—Free from pain.

V.S. to xx. oz.

24th.—Blood buffed and cupped. He feels lighter; tumor unaltered, and very

painful when touched. I then proceeded to secure the femoral artery in the upper third of the thigh, with a single fine ligature. The vessel was of larger size than I ever observed it before: the passage of the needle caused so much pain, that I examined the part with great care for any nerve which might be in danger of being included, but could observe none. On the knot being tightened, he felt very acute pain extending down the whole limb, and which lasted several minutes. The wound was united with numerous fine sutures. The pulsation of the tumor immediately ceased, but its size was not immediately much altered. No other change took place in the limb, and assiduous friction was kept up for several hours.

25th.—Has passed a tolerable night, with occasional pain, from which he is now quite free. The tumor, which is greatly diminished, is still very tender; limb's appearance and temperature natural; pulse 96, hard; tongue white.

R Tinct. Digitalis \mathfrak{m} v.; Magnæ Sulph. 3j.; every 6 hours.

26th.—Has had some pain extending down the leg during the night, and complains of a constant numb, yet painful sensation, in the upper two-thirds of the tibia. The wound is entirely united, excepting the exit of the ligature, and without least inflammatory blush. Pulse 84; skin cool.

Pergat, and an opiate, at night.

27th.—Very little pain, but does not sleep. Pulsation is distinct in the tumor, and in the dorsal artery of the foot. Pulse 90, firm.

V. S. to x. oz.. Pergat.

28th.—Pain lessened; pulsation not at all increased; pulse 86, soft. A copious deposit of lithic acid sand in his urine; blood buffed and cupped.

29th.—Pulsation in the tumor not increased, but he has considerable pain and tenderness in it; pulse 86, much softer than it has been. The force of the circulation generally appears to be diminished.

30th.—Tumor not so tender; pulse 84, soft; tongue clean. He does not sleep, notwithstanding a strong opiate, and has startling dreams. In the evening, the pulsation of the tumor having become more evident, pounded ice in a bladder was applied to it, and 12 oz. of

blood taken from the arm; and at night he took a grain of muriate of morphia.

31st.—Has passed a good night, and is free from pain. Blood taken last night buffed and cupped, with a small coagulum. Pulsation very indistinct in the tumor, and hardly to be distinguished in the foot. No pain or tenderness in the tumor. His urine still deposits a copious lithic sand.

R Magnes. Sulph. ʒi. Calcinat. ʒss. T. Digitalis m̄ vij., 6tis horis.

August 1st.—Pulsation and size of tumor very much diminished, and he complains of very acute pain in the extremity of the left thumb, which is a little swelled.

Hirudines xij. Poultice.

2d.—No clear pulsation to be detected in the tumor; thumb and middle finger very painful—apparently from some gouty affection.

Hirudines xxx., which in the evening had not afforded much relief.

Adde Vin. Sem. Colch. ʒss. Sing. haustibus.

4th.—Hand easier; leg free from pain.

5th.—Hand well; no pulsation in the tumor, and very indistinct in the foot; urine loaded with lithic acid.

6th.—Has rheumatic pain in the knee, which prevents sleep.

Pergat.

7th.—Rather more pulsation in the tumor; the passage of the gravel causes much pain in the urethra.

V.S. ad ʒxij.

8th.—Blood buffed and cupped; knee less painful; sand very copious.

Adde Liqueoris Potassæ, ʒss. haustui. Omitt. Magnes. Sulphas.

9th.—Pulsation can be felt only on the inner side of the tumor; urine with less gravel, and smells strongly.

11th.—Free from pain. The ligature remaining firm, was tied round a piece of bougie, in order to keep up extension, and on the next morning was found detached.

15th.—Has occasionally darting pain about the wound, where there is some hardness; it has been long healed, excepting at the exit of the ligature. The popliteal tumor has been stationary the last few days, and still obscurely pul-

sates; it is free from pain, but prevents full extension of the limb. A bandage was applied from the toes upwards, with a compress over the tumor, but the pressure could not be long borne.

22d.—Has no complaint but of slight pains in the knee; tumor much the same, and still pulsating; the bandage and compress have been applied whenever they could be borne.

23d.—Has great pain about the heart, and more than he had in the knee. The heart's action is violent, and the bellows sound loud in the situation of the left ventricle.

V.S. ad ʒxij. C. C. regioni cordis. Hirudines xij. genu.

In the evening the pain about the heart was much relieved; knee much the same. Blood buffed, and slightly cupped.

Vin. Colchici, ʒj.; Muriat. Morphicæ, gr. j. h. s.

24th.—The pain in the knee continues, but he has none about the heart.

R Ext. Colchici Acetat. gr. ss.; Ext. Hyosciam. gr. iij.; Morphiæ Muriatis, gr. ʒ. Ter die.

Sept. 4th.—The tumor very small, and quite free from pain or pulsation. He still feels, occasionally, pain in the inner side of the knee and tibia, where there is also some degree of numbness. A small fistulous opening still remains in the wound.

10th.—A few drachms of pus escaped suddenly through the small opening in the wound, since the discharge of which all pain has left him, and on the

12th.—He was discharged quite well, having perfect power of flexion and extension. The femoral artery can be felt pulsating to within an inch and a half of the spot at which the ligature was applied, and pulsation is very distinct on the dorsum of the foot. Scarcely any remains of the tumor are to be found, more than a little fulness in the ham, and slight induration; no pulsation whatever. He feels well in all respects, but the bellows sound still accompanies his heart's action.

I had prepared to send this account for insertion in your journal some time ago; but as the man, about the time I had it ready, returned to the hospital labouring under an attack of acute rheu-

matism in the arms, and also affected with severe rheumatic pericarditis, I delayed the sending of the history of the case until he should have recovered from the attack, which at one time appeared doubtful. He is still labouring under considerable affection of the heart, and rheumatic pains in the hands and arms; his leg remains well.

A NEW METHOD OF PREPARING IODIC ACID.

To the Editor of the Medical Gazette.

SIR,

I SEND for insertion in your valuable periodical a new method of obtaining iodic acid; it will be found to be cheaper and safer than the mode used by Sir Humphry Davy, and afford a purer acid than the plan proposed by Gay Lussac. I say purer, since, from some late experiments, which I intend to repeat, I am led to conclude with Sir H. Davy, that the acid of Gay Lussac is sulpho-iodic acid.

Put one atom, or 124 grains, of iodine into a bottle containing 24 ounces of water, and pass chlorine, previously washed, through the mixture, until this having undergone various changes of colour, from orange-red to yellow, shall have become as colourless and transparent as water. The solution is then to be carefully heated to 212° Fahr. to expel the excess of chlorine, and five atoms, or 690 grains, of pure oxide of silver being added, the mixture is to be boiled for ten minutes, filtered, and cautiously evaporated to dryness. The product is pure iodic acid, and must be kept in a well-stoppered phial.

Since the liquid obtained in the first part of the preceding process not only possesses the taste and smell of muriatic acid, but will also afford that acid by distillation, it is but reasonable to conclude that the liquid itself is a mixture of muriatic and iodic acids with water, and consequently that the chloriodic acid of Sir Humphry Davy is merely chloride of iodine, with a variable quantity of iodine in excess. I have not, however, been able to combine chlorine and iodine directly in the proportions necessary to produce these acids (muriatic

and iodic) on being dissolved in water, but I have no doubt that this may be done in a sufficiently reduced temperature. In the most considerable experiment which I made on this subject, 50 grains of iodine absorbed 41.5 cubic inches, or about 31 grains of chlorine. The orange-coloured product thus obtained, on being dissolved in water and exposed to the light for a few days, deposited nearly 8 grains of iodine, and became of a pale yellow colour; in which state it still remains, and gives, with nitrate of silver, a white precipitate, soluble in ammonia.

As the iodate of ammonia is not described in any work on chemistry with which I am acquainted, I think it right to state here that it is a highly crystalline granular powder, and possesses but little solubility.

The iodic acid is open to so many objections as a test for the presence of morphia, that no reliance ought to be placed on it, since it affords a precipitate not in any way to be distinguished from that by morphia with the following substances—viz. sulphocyanic acid; the sulphocyanates of potash and soda; saliva, doubtless from the presence of the above; urine, perhaps from the same cause; albumen; arsenite of potash; tartarized antimony; and the proto-salts of iron, tin, and manganese. The importance of these facts, in a medico-legal point of view, is considerable.

The solution of muriatic and iodic acids will answer equally well as iodic acid alone, for the purpose of testing morphia.—I am, sir,

Your obedient servant,

LEWIS THOMPSON,
Member of the Royal College of Surgeons.

Roe-Buck Place,
Great Dover Road, Nov. 2, 1836.

EFFECTS AND USES OF SMOKING.

To the Editor of the Medical Gazette.

SIR,

If you think the following observations upon the effects of smoking worth publication, their insertion in your journal will oblige, sir,

Your obedient servant,

FREDERIC ROBERTS,
M.R.C.S.

Galt-y-Beren, Carnarvonshire,
October 28, 1836.

The properties of the tobacco plant are well known to be those of acting upon the heart, producing an irregularity in its action, which is at first increased, and afterwards becomes diminished, or altogether suspended, whereby the circulation is stopped, and syncope produced. Nausea, vomiting, vertigo, tremors, dilated pupil, cold perspirations, a very feeble pulse, with great anxiety and dejection, are the symptoms of an over-dose of the *infusion*, which Sir B. Brodie has proved to differ in its action from the *distilled oil*, by reason of the latter containing no *nicotin*; and “whether applied to the tongue or injected into the intestines, does not stop the action of the heart and induce syncope, like the infusion of tobacco, but that it occasions death by destroying the functions of the brain, without directly acting on the circulation. In other words, its effects are similar to those of alcohol, the juice of aconite, and the essential oil of almonds.” Upon these principles, it is exhibited as an antispasmodic and diuretic in dropsy and dysuria. Its good effects in asthma, colic, ileus, and strangulated hernia, prove its antispasmodic properties in an eminent degree. It has a powerfully sedative influence upon the nervous system, as is familiarly exemplified by its relieving appetite when chewed. Upon the same principles also, I shall endeavour to show the effects of *smoking*, which greatly vary in different constitutions.

Smoking, when moderately indulged in, relieves tension and constrictions, by gently relaxing muscular fibre; and by its action on the heart it moderates the circulation, and determines to the centre, thereby rendering the circulation in the capillaries less active; which, I suppose, was the reason that led to its employment lately on the continent in scarlatina. A very frequent effect of smoking is to excite the action of the intestines; indeed, “suppositories of the leaf are used in India, to provoke the action of the bowels in children.” Its operation in this manner is effected by *increasing the secretion of the mucous membrane of the intestines, as the exhalation by the skin is diminished*. The constriction of the skin, from disorder of its function, is succeeded by a relaxation, if the smoking is continued or indulged in, by one of a relaxed habit, or

of an irritable stomach. However obnoxious and worthless this plant may be considered, there is no doubt that the Creator intended it, like every thing else, for some purpose, and has in like manner placed it where it would be most required.

Upon the principles, then, on which we have shewn this plant to operate, it must be considered as a natural provision for man against the evils which the nature of his climate subjects him to: whereupon we find tobacco growing in a country where man, from excessive heat, becomes exhausted by profuse perspiration, from which this leaf so agreeably relieves him. The evil of a slight determination to the centre, which might occur, would be counterbalanced by the good effects of checking the profuse sweating, and the action on the bowels. The custom of smoking by Europeans in hot climates must, in this manner, be frequently beneficial; as in moderating the perspiration, the excessive secretion of bile, from the sympathy which exists between the liver and skin*, is obviated, thus preventing fevers (especially bilious) and other diseases in which the liver is implicated. It must also diminish the liability to those cutaneous diseases which occur in hot climates, from excessive action in the vessels of the skin.

Its ill effects, especially in a cold moist country like our own, are evidently frequent and numerous; it checks the perspiration, produces nervousness, a flabby constitution, congestion in the larger viscera, and its consequences; predisposes to cutaneous diseases, which arise from want of action in the skin; and aggravates those already existing, besides others, in which the functions of the skin are imperfect, particularly chronic inflammatory dyspepsia, which is accompanied by a dry skin. It impairs digestion, by expending the saliva, the increased secretion of which, discharged by spitting, diminishes the cuticular exhalation — a circumstance which may give rise to a foetor of the breath, by morbidly increasing the exhalation by the lungs.

* In immoderate exhalation by the skin, the secretion from the liver differs from that of other organs, by being *increased*, and not *diminished*.

HOMŒOPATHIC IMBECILITY.

DISEASES OF THE METROPOLIS.

To the Editor of the Medical Gazette.

SIR,

THE almost total absence of inflammatory disease from the metropolis, during the last five or six years, has enabled the converts to homœopathy to revel in its mysteries with perfect impunity. Had these individuals been men of no standing in the profession, they might have been allowed to use their atoms without interference; but when we find gentlemen of professional attainments, and of literary acquirements too*, advocating this empirical study, it is high time the public should be informed, through their professional friends, of the false security of such treatment, and to pause before they confide in the forty-eighth part of a grain of blue pill, or the twelfth part of a grain of camomile flowers, removing an attack of inflammation. To show how completely free the metropolis has been from all active disease during the last year, I would mention, that in the two large public establishments (not hospitals) of which I have the care, there have been admitted 14,000 persons. I have only had occasion to use the lancet three times: twice in cases of phrenitis from excessive drinking, and once in a case of fractured skull; the deaths in the 14,000 amounting, in the year, to twenty-six; which, taking into consideration the dissolute and abandoned characters of the majority, is unusually small.

I hope, sir, you will consider it your duty to assist in dispelling the delusion under which the public are suffering, and that the profession will not cease to heap ridicule upon the homœopathist, till he exclaims in despair, "*Non tali auxilio—miseris succurrere disco.*"—I am, sir,

Your obedient servant,

HENRY WAKEFIELD.

Lansdowne Place, Nov. 2, 1836.

TENANCY BY THE COURTESY.

To the Editor of the Medical Gazette.

SIR,

I HAVE with pleasure witnessed the interest which you take in every subject

* Our correspondent means to be complimentary.—ED. GAZ.

relating to medical jurisprudence, and I am sure, therefore, you will not deny me the opportunity of obtaining, through the medium of your excellent journal, an answer to the following question:—

Is *tenancy by the courtesy* still a part of the law of this country?

In a respectable Quarterly Review, it is stated that the law of "*tenant by the courtesy* has been recently annulled*." It is possible that the reviewer may be right; but it would have been more satisfactory had he, instead of contenting himself with a bare assertion, given the authority upon which he rested it. I am induced to think he is wrong, for the following reasons:

1. Mr. Chitty, in his work, published in 1834, speaks of it as then in existence†.

2. No mention is made of any alteration in the law in the statutes of 1834 and 1835.

Not having yet seen the statutes for 1836, the act annulling it, if it be annulled, as the reviewer states, may be among them.

One of your correspondents, in a letter addressed to you in August, 1833‡, remarks, that "the law with regard to tenancy by courtesy has been completely changed, in consequence of the first report of the Law Commissioners on real property; so that it will no longer be necessary to prove that a child has lived for a *second or two* in order that the father should enjoy the tenancy by courtesy." He also speaks of Acts (Bills?) being brought into parliament by the then Solicitor General (Sir J. Campbell) on the subject; but whether the Bills were brought in or not, there is no evidence of their having passed, as your correspondent intimates. It is, indeed, hardly likely, that, had such an alteration been made, Mr. Chitty would have failed to notice it in a work published the year following your correspondent's communication. So far from this, Mr. Chitty refers to the old law as still in existence; and the statutes of 1834 and 1835 contain, as far as I can perceive, no enactments to the contrary.

The question is of material importance in regard to the survivorship of

* British and Foreign Medical Review, Oct. 1834, p. 408.

† Chitty's Medical Jurisprudence, p. 435.

‡ MEDICAL GAZETTE, vol. xli. p. 677.

children, either *during* or immediately *following* birth. Perhaps either yourself or some of your numerous correspondents will be able to remove the doubt which seems to me to hang over the subject.—I am, sir,

Your obedient servant,
M. J.

London, Oct. 24, 1836.

[We can give our correspondent a categorical answer: there has been no alteration of the law of tenancy by the courtesy. Neither the statute 3 and 4 Will. IV. c. 106, affecting inheritances, nor the preceding chapter, 105, amending the law of dower, disturb in any way the courtesy as previously established; and the bill which was prepared in 1833, to amend the law of tenancy by the courtesy, was never carried.—ED. GAZ.]

MUSCLES OF THE EYE-BALL AND THEIR NERVES.

To the Editor of the Medical Gazette.

SIR,

MR. WALKER's statement and mine are now before the readers of the GAZETTE; I do not, therefore, feel it at all incumbent upon me to enter into any further explanation of the subject until the publication of my paper in the next volume of the Transactions of the Provincial Medical and Surgical Association. I trust the perusal of that paper will render any such further discussion as could be founded on the views given by Mr. Walker in his letter of Sept. 20th, totally unnecessary. I shall for the present be contented with briefly mentioning the discoveries to which I have presumed to lay claim. These are different explanations of the functions of the third, fourth, and sixth pairs of nerves from any previously given, founded on a careful examination of the muscles which these nerves supply in reference to their separate and combined action.

I would ask, then, if this statement be correct, am I not right in requiring more acknowledgment from one who has made use of these views than is contained in Mr. Walker's remark, nearly at the end of his letter—that "Mr. Hunt first suggested the probability

that the complexity of the nerves of the orbit was connected with the varied motions of the two eyes which I have pointed out"?—I am, sir,

Yours respectfully,
R. T. HUNT.

Manchester,
October 22, 1836.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Icones Plantarum; or Figures, with brief descriptive Characters and Remarks, of New or Rare Plants, selected from the Author's Herbarium. By SIR W. J. HOOKER. 8vo. Part I. London, 1836.

Few persons, during the last quarter of a century, have laboured more assiduously, with pen and pencil, in the cause of botany, than Sir W. J. Hooker; none more successfully. The state, by bestowing its honours upon him, has borne testimony to the extent and value of his exertions, and the esteem in which they are held by all scientific persons is a farther confirmation of their worth. Eager, apparently, to justify yet further his claim to such general homage, he now comes forward with a new work, which, if not so elegant and ornamental as some of its predecessors, is calculated to be equally useful. Indeed, we regard the idea of this work as a singularly happy one. "It has often occurred to the author of the work now announced, that by means of lithographic drawings, executed on moderately-sized paper, an important series of plates of new and little-known plants might be offered to the scientific world, at a price so moderate as to bring them within the reach of almost every one interested in the subject." Nor is it the zeal alone of the author that we are called upon to notice with commendation, but likewise the liberality of the publishers. "Even should the publication meet with the success that his fondest wishes might anticipate, yet the price set upon it is so low as to forbid any hope of profit; and he is anxious to express his acknowledgments to the publishers, for kindly guaranteeing him against any pecuniary risk in the undertaking." In con-

sequence of this, we have here 58 well-executed lithographic representations of a considerable number, nearly 100, rare plants, for the plates devoted to the mosses contain sometimes six species, at a price incredibly low. Yet a prudent caution, rising out of sad experience of the slender encouragement given to illustrated scientific works in this country, has occasioned the impression to be limited to 300 copies. We trust, however, that the increasing zeal for natural history, diffusing itself over the country under the influence of the British, and many local Associations, will lead to such extended patronage of this work, as will justify ere long a second edition. Meanwhile, those who feel desirous of possessing these beautiful representations of plants, of very diversified form and structure, from trees down to Ferns and Mosses, will do well to make application while they are yet to be had. By the plan adopted in the letter-press, when the work shall have been completed, the plates, and the descriptions of them, may be arranged and bound up in whatever way the possessor may prefer. This is a great advantage, but we trust the series may be so extended that some hundreds of plates shall be published before any one is required to decide how he would wish them arranged.

On Disease of the Hip Joint, with plain and coloured Plates. By WM. COULSON, Consulting Surgeon to the London Lying-in Hospital, late Surgeon to the General Dispensary, &c.

MR. COULSON has devoted considerable attention to the diseases of the hip joint, and two clinical lectures on the subject, which he delivered about five years ago, will be found in one of our early volumes. Since that time, we learn from the preface, that his opportunities of investigation have been increased by his appointment to the Board of the Sea-Bathing Infirmary — the result of all which is the monograph before us.

The anatomy and physiology of the hip joint are fully described in the opening chapter; but of this, the only portion to which we shall allude, is the account of some experiments of Weber's, in reference to the means by which the head of the femur is retained in the acetabulum, and which would seem to

shew that atmospheric pressure has a considerable influence. The German authority says, that a body was placed in such position as to suffer the thigh to hang freely over the table; the muscles and ligaments were then cut through, and yet the thigh did not fall; on the contrary, the articular surfaces remained in close apposition. A small hole was made in the acetabulum, so as to allow the air to enter, and straightway the limb dropt as far as the capsules would suffer it, and this, although the muscles and ligaments were not divided. The head of the bone was then re-adjusted in the socket, and the aperture in the acetabulum stopped with the finger; the bone was now retained *in situ*, but once more fell out on the finger being removed. These experiments have been repeated by Mr. Coulson, and with similar results "as regards the most essential point." He adds, that the extent to which the head of the bone can be removed from the acetabulum by the admission of air, the effusion of fluid, or by force, somewhat exceeds an inch. By the latter, it is difficult or impossible to effect so great a lengthening, unless the limb be rotated inwards at the time.

Disease of the hip joint is regarded by Mr. Coulson as the mere external demonstration of a pathological condition, involving the general system, and consequently any views limited to the part itself are too confined. The vital or nutritive functions are those which he believes to be primarily affected; while the secretions are remarkably implicated in almost every instance. This view leads him to distrust the efficacy of topical remedies so generally used, which, indeed, he speaks of as having produced an exacerbation in almost every case in which they have been employed.

Where the secreting organs are large, and the locomotive proportionally small, then it is that, according to some authors, disease of the joints, especially the hip, are most readily developed; and he instances the Saxon population of England and Holland in illustration, having large trunks and feeble extremities. Camper states that in his time as many as one in twenty-eight of the Hollanders became lame. This principle is adopted by Mr. Coulson, and worked out by numerous, and some of them ingenious, remarks, the sum of the

argument being, that the affection of the joint is "not a consequence, but a mere external symptom, of constitutional disease."

It is proper to add, that while treating of the pathology, Mr. Coulson brings successively before the reader the opinions of all the best authorities, both at home and abroad.

The morbid anatomy of the hip-joint is interesting, and a very good account is given of it. The changed appearances vary more in degree than in kind, marking the extent of the mischief rather than difference in its nature. The chief changes are inflammation of the synovial membrane, its thickening, ulceration, and perforation; preternatural secretions into it of synovia, lymph, or pus; its entire destruction. The ligamentum teres becoming ulcerated or absorbed. The articular cartilages abraded, ulcerated, or entirely removed. Destruction of the cartilages being replaced by an ivory deposit; portions of them being found loose and floating. Widening and shallowing of the socket; the bone becoming denuded and carious, or ulcerated. Lessening of the head of the femur, and contraction of its neck; softening of the bone, and deposition in its cancelli of yellow caseous matter, or of transparent fluid. The most striking feature in this form of disease is the absence of the secretion or deposition of bone; being, in this respect, very different from common inflammation, in which (especially when chronic) the ossified deposit is increased.

A clear account is given of the symptoms of hip-joint disease, but it does not contain such novelty as to warrant our dwelling upon it.

In the treatment, it is held by Mr. Coulson to be of great importance to distinguish between those cases which occur in strong and those in scrofulous patients; an observation in keeping with what has been made by other writers on the subject.

The subjects are illustrated by six well-executed lithographic engravings.

Physiologie des Menschen [*Human Physiology*.] Von FRIEDRICH TIEDEMANN, Lehrer der Anatomie und Physiologie an der Univ. zu Heidelberg. Dritter Band. Darmstadt, 1836. Schloss.

THE excellence of the two former volumes stamped a character on this work, and created a strong desire for its con-

tinuation. The third volume has just issued from the press, and will, we think, be found as replete with interest as its predecessors. It treats exclusively of the function of digestion and of aliment, giving an account of all that has been ascertained on the subject, both through the experiments of the author, and of his contemporaries.

MEDICAL GAZETTE.

Saturday, November 5, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE POOR LAW COMMISSIONERS' TREATMENT OF A MEDICAL OFFICER.

Our remarks on the Harpenden affair—an affair to the last degree damnatory of the *amended* poor-law system—were founded on a document issued from Somerset House. On their own shewing we proved that nothing could be more vile than the conduct of the Commissioners, in attempting to throw the heavy blame attaching to their proceedings in that case off their own shoulders on those of their medical officer. They made him, or endeavoured to make him, their scape-goat, fastening the iniquities of their system on his back, and then turning him adrift. But we find we were only half-informed when we made those observations: our information was *ex parte*, being altogether derived from the *honourable* Commissioners' statements. We were not aware to what an extent official papers may be made to lie, when it serves the purpose of the party in office to give them a certain colouring.

A letter from Mr. Kingston, of St. Alban's, has since appeared in the newspapers, throwing quite a new light on some of the circumstances connected with the affair. This gentleman, it will perhaps be recollected, was the medical officer so unceremoniously dealt with by

the Somerset House authorities; and certainly his version of the story, which appears to have all the impress of truth upon it, forms a remarkable comment on the statement of the commissioners. We freely confess that we were premature in our censures of some part of Mr. Kingston's conduct; but we were betrayed into severity by adopting too unhesitatingly the official report, never once thinking that it could be so grossly unworthy of credit. The lesson may be useful: we shall know in future how to appreciate productions coming from the same quarter.

The letter, in the first place, confirms all the chief facts relative to the Commissioners' trickery; and a more insidious, disgraceful trick, never was attempted to be practised upon the public. The main circumstances of the case cannot be too fully exposed. The public indignation was gathering into a storm: in addition to the manifold instances of heartless cruelty exercised towards the poor under the "amended" system, the case of a wretched woman absolutely left destitute of all medical assistance, and whose death was clearly owing to the mischiefs of the new law, was about to lead to a crisis, when the conscientious functionaries resolved to allay the ferment, at whatever risk. They could hit on nothing better than to sacrifice one of their officials. After due parade and preparation, they proceed. They throw their unfortunate hireling overboard—a sort of tub to the whale: but the whale is not so easily deceived; and the tub itself turns up eventually to their utter discomfiture and confusion.

Mr. Kingston has well exposed the whole train of machinations employed by the wily utilitarians. They took every advantage of him. He was entrapped into a conference at Somerset House with the secretary of the Commissioners, and while he thought he was offering an explanation simply of his

conduct, every word that dropt from his lips was taken down by a short-hand writer, and given to the public as his *defence*. This, as Mr. K. very properly says, is what would not be done with the greatest criminal in England: if Mr. K. were regularly on his trial, he would be apprised that his confessions or statements were to be preserved, and he would be warned to be cautious to say nothing that might tend to criminate himself. But no: neither was any such warning given, nor were his depositions read to him, nor was he allowed to read them over, so as to guarantee their correctness: the first notification of the proceeding was, seeing his private conference with the secretary in Somerset House committed to the world through the newspapers! There might still be some excuse, if the thing were correctly done: but Mr. Kingston has pointed out some egregious misrepresentations: things were put into his mouth which he never uttered. Such at least was the haste of the zealous secretary to make a case for the public.

Among other points, they represent Mr. Kingston as saying, that he would conceive himself justified in attending more promptly to the call of the Squire, or any rich patient, than to the order of an overseer. Mr. K.'s obvious meaning was that he would consider the Squire's the more pressing case of the two, unless the order were duly backed by a request to be prompt, the case being really serious; for the Squire would not send unless there were some actual urgency, whereas the pauper's order has been often found vexatiously deceptive; the patient being probably at work, and no way ill, when the medical man, in obedience to the order, has arrived.

Again: Mr. Kingston is misstated as describing himself *thirty* years connected with parish practice; *thirteen* years were his words. Can there be a more convincing proof of the eagerness of the

party to make out a case? In their haste to come before the public with something in the form of an excuse, they have not the common decency to see that their officer is correctly reported.

But if Mr. Kingston were taken by surprise, not so was Mr. Secretary Chadwick: all the interrogatories were duly arranged for the occasion; the matter as well as the tone and temper. The object is manifest to all who read the published account of the conference. It was attempted to wring from Mr. Kingston an admission that parish medical duties were more strictly enforced under the new system than the old; and it was conceived that such an admission, coming from an officer of thirty years' experience, would be much stronger than coming from one of only thirteen.

The letter of Mr. Kingston, however, is clear upon the point of relative merits: he speaks positively on the subject, and, from his experience of both states of things, he is perfectly competent to give an opinion. All the strictness and severity of the present system he admits; but he distinctly denies its superiority. The poor were better attended to under the old system; there were more medical officers, and greater liberality in granting orders for relief. Under the new regime the amount of medical aid is greatly limited: the hands are fewer, and much worse paid, while the duties imposed on those few and ill-paid officers are beyond the powers of men of ordinary physique. The consequence is, that when an order is granted, as it generally is, with a most niggard disregard of the pressing wants of the unhappy paupers, there are many chances against its being effective; the means being utterly inadequate to the end proposed.

But on this head we beg to refer our readers to the excellent letter of an "Old Navy Surgeon," at page 204.

MADAME MALIBRAN.

MYSTERY still hangs over the decease of this ill-fated child of genius. It was asked in the *Times* a few days ago, whether M. de Beriot had not abruptly left Manchester with all her apparel and property ere she had ceased to breathe; and to those interrogatories we take leave to add a few others which relate to the medical proceedings.

Is it true, or rather is it not true, that when Dr. Bardsley was so unceremoniously discharged, his patient was going on favourably,—in fact, that she was then nearly or altogether convalescent?

Is it true that it was afterwards thought desirable by some *coup de pratique* to enable her to complete her engagement?

Is it true that manual interference was had recourse to for the purpose of effecting premature delivery, and that this failed to produce any other effect than that of overwhelming exhaustion?

And, Is it true that when the body of the unfortunate deceased was receiving the last offices from the strangers to whom she was left, the relaxing hand of death completed what art had been unable to accomplish?

These are questions of interest to science, to which we trust either M. Belluomini or Mr. Lewis will reply. They will perceive that a great practical lesson is involved, and although they have doubtless fully learnt it, the medical world is still kept in suspense.

OPERATION AT THE NORTH LONDON HOSPITAL,

IN PRESENCE OF THE PATRON.

On the 21st ult. Mr. Liston performed one of those operations on the face, for his boldness and dexterity in accomplishing which, that gentleman has become remarkable.

The patient was a female, named Mary Griffiths, aged 20. The tumor,

which was of fibrous character, originally appeared seven or eight years ago upon the upper gum, above one of the incisors, and progressively increased, notwithstanding various efforts made to extirpate it at different times. On her admission into the North London Hospital the tumor and ulcerated surface occupied the site of the upper lip, nose, and great part of both cheeks, particularly the left. The whole was dissected out, and large portions of the upper maxillary and cheek bones were also removed, apparently with great ease, by means of the bone nippers. Astonishingly little disfiguration of the face remained after the flaps had been brought together; and the patient has since continued to do well.

A considerable sensation (to use the language of the newspapers) was caused by another production, of still more anomalous character, and which likewise was brought into the operation-room for the inspection of the pupils. On closer examination this proved to be neither more nor less than the person of Thomas Wakley, Esq. M.P. Patron and Puffer of the establishment, and Slanderer-General of all the other schools in the metropolis, who had kindly consented to appear on this occasion in *propria personâ*, in order to oblige the Professors, and to prove to the world that there is one hospital in London into which he is admitted!

We understand that it is in contemplation to perpetuate the event, by erecting in the theatre a bust of the *honourable* Patron. The inscription has not yet been finally decided upon; but the learned printer to the "University" has suggested, as being at once neat and appropriate, his own motto—

"ALERE FLAMMAM."

A WELCH MEDICAL SOLON.

"LATE INFANTICIDE AT THE BISHOP OF WORCESTER'S PALACE.—Mr. C. Llewellyn, surgeon, of Llanymyneich, says,

in reference to the woman accused of this crime—"I am sorry to observe that Charlotte Grounsel, an inmate of the Bishop's palace, has, in my humble opinion, been a sufferer from the statement of her case before the Coroner's jury. I do not pretend to account how, or in which way, the wound on the child's neck was inflicted; but looking at it correctly, and in an anatomical sense, it could not have caused the child's death; neither do I think that the mere floating of the lungs in water is a proof of its having been born alive; therefore, in my opinion, the *post-mortem* examination was not calculated to throw any light on the matter. The floating of the lungs in water has been long exploded as a medical test.'"—*Berrows' Worcester Journal*.

This is a sample of the sort of *medico-legal* information which that "best possible public instructor"—the newspaper press—is in the habit of diffusing. The circumstance of having the name of a professional man attached to it, no doubt gives the paragraph an air of authority. But who, we should like to know, is this Mr. Llewellyn, who plays "will-o'-the-wisp" on the occasion? If he be not a mere *nominis umbra*, perhaps he would favour us with a reason for the opinion which he volunteers so benevolently. To put the best construction on his conduct, he appears strongly disposed to save the accused at all hazards: but he is a very wrong-headed man if he thinks his bare assertion is to have any weight against the strong presumptions derivable from observation and experience. He is certainly a very ignorant or very dishonest person to state that the hydrostatic lung-test has been exploded: every well-informed medical man knows to the contrary. The phenomenon of the floating or sinking of the lungs, when observed with proper caution, is capable of affording a high degree of presumptive evidence as to the fact of live or still-birth; and when taken in conjunction with other appearances, of which Mr. Llewellyn seems to have not an idea, may constitute proof of the most convincing character. We pretend not to pronounce any opinion respecting the particular case of Charlotte Grounsel, for whom Mr. Llewellyn's sympathy is engaged: we should have facts before us, to warrant such a proceeding. Our

only object in noticing the above paragraph is to show what silly stuff sometimes comes before the public, under the sanction of a medical name. As to Mr. Llewellyn, if their really be such a person, we recommend him to look into his books, or ask some respectable brother practitioner what may the hydrostatic lung test mean. Till then, he had better throw a veil over his ignorance, and remain quiet.

THE NEW PHARMACOPŒIA.

THE Order in Council which recently appeared in the *London Gazette* was a necessary preliminary before the new Pharmacopœia could be published. We understand that it will now appear almost immediately.

THE UNIVERSITY OF LONDON.

THE Charter of the new University received the sign manual a few days ago. It requires, however, to be confirmed by Parliament before the parties in whose favour it is granted can enforce its provisions in the courts of law.

LECTURES ON

LOCAL HYSTERICAL AFFECTIONS,

Delivered in the Medical Theatre of St. George's Hospital,

By SIR B. C. BRODIE, BART. F.R.S.

LECTURE I.

Hysterical Affections of the Joints, particularly the Knee and Hip—their Characters—not confined to the Female Sex. Hysterical Disease of the Spine—Illustrations.

GENTLEMEN, — In commencing my course of lectures for the present season, it is not my intention to occupy your time by offering you any introductory observations. It seems to me that you hear a sufficient number of introductory lectures already, and, if I were to add to the list, I must inevitably trouble you with the repetition of what has been already said to you by your other teachers. For this reason, I think it advisable to enter at once on the consideration of some subject connected with practical surgery; and I am the more inclined to do so, as my course of lectures being of limited extent, I cannot well afford to devote any of them to other purposes.

I call these clinical lectures, because they are intended to illustrate the history and treatment of particular cases in the wards of the hospital. I do not intend, however, to confine myself absolutely

to lectures of this description, and I may sometimes call your attention to a particular disease, or order of diseases, without reference to any of the patients who may be under my care at the time. My general rule will be to deliver lectures that are truly clinical; but the rule will have some exceptions, and one of these will occur in the beginning of the course. Those gentlemen who attended the hospital during the last spring, will remember that I promised to give some lectures illustrative of those local hysterical affections of which I have occasionally spoken to you in the wards. I fully intended at that time to redeem my promise during the summer months, but various circumstances having prevented my doing so, I propose to redeem it now.

When I was formerly engaged in the study of the diseases of the joints, having, at the period, to which I refer, few opportunities of investigating the subject except in my hospital practice, I occasionally met with cases in which a particular joint was affected with pain, and a great degree of morbid sensibility, attended occasionally with some degree of tumefaction of the soft parts, although the characteristic symptoms of the ordinary diseases to which these organs are liable were wanting, and the usual consequences of abscess and destruction of the joint did not ensue. For a long time these cases occasioned me great perplexity, and it was not until after I had published the first edition of my *Treatise on the Diseases of the Joints* that the occurrence of the case, which I am about to describe, first led me to suspect the real origin of the symptoms, which I had not comprehended formerly.

I was consulted concerning a young lady who complained of severe pain and a morbid tenderness of the knee, in the first instance attended with no perceptible enlargement of the joint. The remedies which, with such knowledge as I then possessed, I was led to recommend, gave her no relief; and after some time a slight degree of tumefaction took place, depending, as it seemed, either, on a fulness of the small vessels, or on an effusion of lymph or serum into the subcutaneous cellular texture. She had been in this state for a considerable time, when she was seized with a succession of violent paroxysms of hysteria, which terminated in an hysterical affection of the brain; so that she lay in a state approaching to that of coma, with dilatation of the pupils of the eyes. She was now attended by the late Dr. Babington and myself. I do not undertake to say whether the disease yielded to the remedies employed, or reached its natural termination; but, from one or other

of these causes, the patient recovered of the last-mentioned symptoms, and from that time she never complained of her knee.

Not long afterwards another young lady was brought to me, labouring under what had been supposed to be a scrofulous disease of the wrist. The resemblance of this case to that of the last-mentioned patient led me to doubt the correctness of this opinion, and the results proved my doubts to be not without foundation. She also was seized with a succession of violent paroxysms of hysteria; and when, after the lapse of many days, she had recovered from them, the disease of the wrist had vanished.

It seemed impossible to doubt that in each of these cases there was some connexion between the local symptoms and the constitutional disease under which the patient laboured; and a great number of other cases, which fell under my observation afterwards, confirmed me in the opinion; that where there is that state of the general system, whatever it may be, which produces the phenomena of hysteria, it is not uncommon for a particular joint to be affected with pain and morbid sensibility, such as may lead a superficial observer to believe that it is the seat of some serious local disease, although no such disease in reality exists.

In the second and subsequent editions of my Treatise on the Diseases of Joints, I have given some account of these local hysterical affections. I trust that what I have there stated may have been not wholly unacceptable to those, who are engaged in the practice of our art; but the subject is one of great interest both to the scientific pathologist and to the practical surgeon, and believing that I can furnish you with some information respecting it, beyond that which is to be found in my former publications, I am led to call your attention to it on the present occasion.

I have already mentioned, that when my opportunities of studying these diseases were limited to what I saw in the wards of the hospital, these affections of the joints fell occasionally under my observation. Since I have been engaged in a large private practice, they have presented themselves, I may say, without exaggeration, almost daily. This is easily explained. "*Fæminarum enim paucissimæ*," says the sagacious and observing Sydenham, speaking of hysteria, "*ab omni horum affectuum specie prorsus liberæ sunt, si istas excipias quæ laboribus aduetæ duram vitam trahunt*." The liability to hysteria is, in fact, among females, one of the severest penalties of high civilization. It is among those who enjoy what are supposed to be the advantages of affluence and an easy life that we are to look for cases of this

description, not among those who, fulfilling the edict of the Deity, "eat their bread in the sweat of their face." I do not hesitate to declare that among the higher classes of society, at least four-fifths of the female patients, who are commonly supposed to labour diseases of the joints, labour under hysteria, and nothing else.

Frequently the hip joint is the seat of the disease. The symptoms then have a considerable resemblance to those of diseases in the bones or cartilages, yet a minute examination of the case will rarely leave you in doubt as to your diagnosis.

There is pain in the hip and knee, which is aggravated by pressure and the motion of the limb, and the patient often lies fixed in one position on the bed or sofa. You will say, "are not these indications of a diseased hip joint?" But observe further. The pain is not in general fixed in any one part: it belongs to the whole limb. The patient winces, and sometimes screams, when you make pressure on the hip, but she does the same if you make pressure on the ileum, or on the side as high as the false ribs, or on the thigh, or even on the leg, as low as the ankle: and every where the morbid sensibility is chiefly in the integuments. If you pinch the skin, lifting it at the same time off the subjacent parts, the patient complains more than when you forcibly squeeze the head of the thigh-bone into the socket of the acetabulum. As her attention is more directed to the examination, so the pain, which she suffers from it, is aggravated; and if her mind be occupied in conversation, she will scarcely complain of that, which would have occasioned torture otherwise. Then, there is no wasting of the *glutæi* muscles, and no flattened appearance of the nates; and the aspect of the patient is different from that which you would expect to find if the bones and cartilages of a joint were in a state of ulceration. Neither are there those peculiar and painful startings of the limb at night, attended often with frightful dreams, which mark the existence of this last disease. The pain will sometimes prevent the patient falling asleep, but if once asleep, she sleeps soundly for many successive hours; and this state of things may continue for weeks, or months, or even for years, without leading to abscess, or any further ill consequences. There may be a suspicion of abscess, (I have known this in a great number of instances) but the suspicion is never realised. Sometimes there is a general tumefaction of the thigh and nates, the consequence either of a turgid state of the small vessels, or of an effusion into the cellular texture; (I suppose of the former, as the parts do not pit, or remain indented after pressure) but this

is entirely different from the swelling of an abscess. In a few rare instances there is a more defined and circumscribed swelling, but still it is altogether different from that of abscess. There is no perceptible fluctuation, and I can compare it to nothing better than a wheal of urticaria of unusual magnitude. A careful examination will always enable you to distinguish these swellings from abscess. For the satisfaction of others, I have sometimes made a puncture with a grooved needle, or some other convenient instrument, the introduction of which would have detected matter, if matter had existed.

I have said that, in these cases, there is no wasting of the glutæi muscles, and no flattened appearance of the nates. It is, however, not uncommon to find much alteration in the figure of the parts, of another kind; namely, a bulging of the pelvis posteriorly, at the same time that it is elevated on the side of the disease, so as to make an acute, instead of a right angle, with the column of the vertebræ. Of course, under these circumstances, the limb is apparently shortened, and when the patient stands erect, the heel does not come in contact with the ground. A superficial observer may be led to believe that there is an actual dislocation of the hip; and, indeed, it requires a careful examination to enable the surgeon to understand that all this strange distortion is but the result of the predominant action of certain muscles, and of a long-continued indulgence in an unnatural position.

When the symptoms are referred to the knee, they bear a near resemblance to those which have been just described. There is great tenderness of the joint; but the patient suffers more from pinching the skin than from pressure, and the morbid sensibility extends for some distance up the thigh, and down the leg, perhaps as low as the foot and ankle. The patient suffers less from an examination when the attention is fixed on other matters, than when it is directed to the affected parts; and she does not usually complain when pressure is made on the heel, so as to press the articulating surface of the tibia against that of the femur, provided that care be taken at the same time to produce no motion of the joint. In most instances the leg is kept extended on the thigh, whereas, in cases of real disease in the knee joint, it is usually a little bent. These symptoms may continue without any material alteration for an indefinite time; for weeks, or months, even for years, the joint retaining its natural size and figure: but occasionally a slight degree of tumefaction is observable, especially on the anterior part,

over, and on each side of, the ligament of the patella. This tumefaction is not to be confounded with a general enlargement of the joint, by which surgeons are frequently misled, the result not of the disease, but of the remedies employed. I refer to cases which have been misunderstood, and mismanaged by the application of blisters, issues, and a succession of various counter-irritants.

What I have now stated may be sufficient to enable you to understand the nature of the symptoms which you may expect to find where these hysterical affections occur in the other joints of the extremities. The following observations are equally applicable to all these cases, and while they are necessary to complete the history, will be found of use in enabling you to form a correct diagnosis.

The patients thus affected are, for the most part, not much above the age of puberty.

In many instances they labour under some irregularity with respect to menstruation; while in others this function is in no respect different from what it is under circumstances of perfect health.

Those who labour under habitual coldness of the hands, have a weak small pulse, and afford other indications of a feeble circulation, are more liable than others to suffer in this manner; yet it is not very unusual to find these symptoms existing in combination with a florid countenance and a sufficient development of animal heat.

In some instances the joint to which the symptoms are referred, and even the whole limb, is affected with a remarkable alternation of heat and cold. Thus in the morning the limb may be cold, and of a pale or purple colour, as if there were scarcely any circulation of blood in it; while towards the afternoon it becomes warm, and in the evening is actually hot to the touch, with the vessels turgid and the skin shining. This state of things is often a source of serious alarm to the patient, and even to the medical attendant, but I never knew it to be followed by ill consequences.

The majority of the patients thus affected exhibit other proofs of their liability to hysteria. Sometimes they have been subject to the usual paroxysms of hysteria, which have ceased on the local symptoms showing themselves; and a recurrence of the former has been followed by an abatement of the latter, or by complete recovery from them.

Not unfrequently the origin of these symptoms may be traced to a severe illness, which has left the patient in a state of great physical exhaustion; at other

times they are as clearly to be attributed to some moral cause having a depressing influence on the constitution. In like manner the agency of moral causes, especially of those which compel the patient to make much physical exertion, often leads to her recovery. But we must not be led by this last-mentioned circumstance to adopt the harsh conclusion, that these symptoms exist only in those who are of a fanciful and wayward disposition. Young women of the highest moral qualities, and of the strongest understanding, are not exempt from these maladies; but it must at the same time be acknowledged that a cure is more easily attained in them than it is in others.

Although there are none of those painful and involuntary startings of the limbs which occur in combination with caries of the joints, spasmodic actions of the muscles of the limbs are not uncommon in the cases of which I am now speaking. In some cases convulsive motions of the limbs are produced by pinching, or more lightly touching the integuments. These bear no very distant resemblance to the movements of chorea; and it is worthy of notice, that they do not occur if it can be managed, at the same time, that the attention of the patient should be otherwise directed. I have also known them to take place independently of any manifest exciting cause. In the case to which I now more particularly refer, the limb was at irregular periods evidently agitated, so as almost to throw the patient off her couch.

In these cases there is always a sense of weakness in the limb, which for obvious reasons becomes aggravated in proportion as the muscles have been for a longer time in a state of inaction. While the pain and morbid sensibility of the joint are gradually subsiding, this sense of weakness increases, until at last it is the predominant symptom. Under these circumstances the patient often says, "I have no pain, but I cannot walk, because the limb is so weak." Weakness of the muscles, however, is not the only circumstance which interferes with the speedy recovery of the use of the limb in these cases. The tunics of the small blood-vessels, when the limb has been long kept in the horizontal posture, seem to partake of the condition of the muscles; and when the foot is first put to the ground, the skin assumes in consequence a red colour, sometimes amounting to a purple hue, as dark as that which, when limited to a particular spot, is often the precursor of a vesication.

The symptoms which have been described for the most part come on gradually. In the majority of cases they

subside gradually also; but sometimes it is otherwise,—they may vanish without any evident cause. For example: in the year 1834 I was consulted respecting a young lady labouring under a well-marked hysterical affection, simulating disease of the hip-joint. As she was not a resident in London, I had no opportunity of watching the progress of the case, but I have lately received the following account of it from Dr. Mortimer, the surgeon of Haslar Hospital:—Her symptoms had continued nearly unaltered for nearly two years, when one night, on turning herself in bed, she said that she had a feeling as if something had given way in her hip, and from that moment she was quite well.

Another young lady was brought to London for my opinion in October, 1833. She also was supposed to labour under a disease of the hip-joint. After a careful examination of her case, I was satisfied that it was one of hysterical affection, and that there was no actual disease of the joint. I recommended her to leave her couch, to which she had been confined, and to take exercise, especially on horseback. Being a sensible and well-disposed person, she followed this advice, in spite, I doubt not, of a good deal of inconvenience in the first instance. After the lapse of a year, I received from her father the following statement respecting her:—"In pursuance of your advice, she began to use the limb more freely, but with little alteration as to pain and lameness until about six weeks ago, when, by a fall of the donkey on which she was riding, she was thrown over the animal's head, standing on the foot of the lame limb, with her weight upon it. She felt immediately what she describes as a sudden snap, as if something near the joint had given way. This was attended with a violent acute pain, which, however, lasted only a short time. She was replaced on the donkey, and rode home, a distance of four miles. To her great surprise the former habitual pain of the limb had entirely discontinued, and there has been no return of it since. She was able to walk up and down stairs without difficulty or pain, and now walks a considerable distance, using the one leg as freely and as well as the other. Her general health is improving rapidly, although she is still weak. There has been no hysterical fit since the accident; in short, the cure has been complete." However, in this case the cure was not permanent. Three months afterwards the complaint recurred, having the same character as formerly, except that it was not now com-

bined, as it had been in the previous attack, with other hysterical symptoms. She was at this time on the continent, and I have not heard the result of the case.

I have hitherto described these cases as if the symptoms were peculiar to the female sex; but it is not so in reality; and I have known several (though by comparison certainly rare) instances of males being affected in the same manner. I employ the term hysteria because it is in common use, and because it would be inconvenient to change it for another; but the etymology of it is undoubtedly calculated to lead to a great misapprehension with respect to the pathology of that disease. It belongs not to the uterus, but to the nervous system; and there is no one who is much engaged either in medical or in surgical practice, who will not be able to bear testimony to the accuracy of Sydenham's observation on this subject:—*"Quinimmo non pauci ex iis viris qui vitam degentes solitariam, chartas solent impallescere eodem morbo tentantur."*

Hysterical affections, in which the symptoms are referred to the spine, are of very frequent occurrence. Such cases are, in many instances, mistaken for those of ulceration of the intervertebral cartilages and bodies of the vertebræ; and in consequence of this unfortunate impression on the minds of the medical attendants, I have known not a few, but very numerous, instances of young ladies being condemned to the horizontal posture, and even to the torture of caustic issues and setons, for several successive years, in whom air and exercise, and cheerful occupations, would probably have produced a cure in the course of a few months.

In these cases the patient complains of pain and tenderness of the back, to which one or more of the following symptoms may be superadded as those which chiefly tend to mislead the medical or surgical attendant:—Pains in the limbs, especially in the lower limbs; a sense of constriction of the chest; involuntary spasms of the muscles, sometimes induced by change of position, at other times recurring without any very evident cause; a sense of weakness in the lower limbs, so that they are scarcely capable of supporting the weight of the body; and even actual paralysis; difficulty of voiding the urine. When the patient first complains of pain in the back, it must be acknowledged that there is some difficulty in forming a positive diagnosis; but the difficulty vanishes afterwards, so that none but a superficial observer can have any

doubt as to the real nature of the disease. The pain in the back is not confined to a single spot, but it extends to different regions of the spine, and it not unfrequently shifts its place from one part to another. The tenderness of the spine is peculiar. The morbid sensibility is chiefly in the skin, and the patient, for the most part, flinches more when the skin is even slightly pinched, than when pressure is made on the vertebræ themselves. The pain is, in the majority of cases, more severe than in those of real vertebral disease; and the spasms of the muscles have a near resemblance to those of chorea. Where there is paralysis, or a tendency to paralysis, it is quite different from what is observed in cases of pressure on the spinal cord or brain; and I may take this opportunity of observing, with respect to hysterical paralysis generally, that it has this peculiarity—it is not that the muscles are incapable of obeying the act of volition, but that the function of volition is not exercised. The accuracy of this observation will, if I am not much mistaken, be acknowledged by all those who are at the pains of studying these cases with the attention which they so well deserve; and the importance of it in medical and surgical practice is sufficiently obvious. There are still other circumstances which may assist us in forming our judgment; such as the general aspect of the patient, and her condition in other respects; her time of life; the state of the menstruation; and especially the liability to the more common hysterical affection.

Patients with a weak pulse, and cold hands and feet, are, on the whole, more liable to suffer in this manner than other persons. But this is almost a needless repetition. It would be sufficient for me to refer to what I have already stated in speaking of hysterical affections simulating diseases of the joints of the extremities.

I have frequently known surgeons to apply a hot sponge to the spine, believing that if the patient complained of pain on the application, this was a proof of the existence of caries. My own experience leads me to believe that a patient who labours under a nervous pain of the back will complain of the hot sponge even more than one in whom real disease exists. I mention this trifling matter, that you may avoid being misled by it in your diagnosis.

NEW-FANGLED DOCTRINES
RESPECTING THE TREATMENT OF INFLAMMATION.

To the Editor of the Medical Gazette.

SIR,

AT a time like the present, when every thing around us appears to be undergoing a change—when long cherished medical theories and modes of practice are abandoned by some, and looked upon with scorn—it becomes, I think, the duty of professional men to make such strictures upon the new-fangled principles and opinions of the age, as they may think likely to be productive of benefit to the profession, and to their fellow-creatures. I shall, therefore, without further preamble, proceed to make a few remarks upon a paper which was published a short time ago, in a contemporary journal, by Mr. Searle, of Kennington, in which he endeavours to show that the practice usually followed in the treatment of acute inflammatory diseases, being founded upon erroneous principles, is absurd, and therefore ought to be abandoned.

Mr. Searle sets out by pronouncing a terrible condemnation upon the antiphlogistic plan of treatment. He then lays down certain rules for the treatment of inflammatory diseases, which, he says, are confounded “in science, in reason, and in nature,” and in doing so, he divides the treatment into what he calls the treatment of the constitution, and the treatment of the local disease. Under the head of the treatment of the constitution, we are told that the predisposing cause of inflammatory fever being either a reduced or a low grade of muscular power, in order to prevent its accession, depletory means, which considerably diminish that power, should be carefully avoided; that the diet should be nutritious, without being unnecessarily stimulating; and that exercise, which is a salutary mode of preventing pyrexia, may be had recourse to in many cases during the first, and after the latter stages of, internal inflammation.

When inflammatory fever has commenced, measures for the removal of its predisposing cause, similar to the above, which are recommended for the prevention of the fever, Mr. Searle says ought to be adopted, limited only by the disability of the patient to pursue them so fully. Animal food in a solid form, he states, cannot, in general, be taken, if the fever be acute, but “milk, whey, beer, wine and water, eggs, or good broth, can be taken in small quantities, and frequently;” and he adds, that if nourishment be judiciously and

fearlessly administered, the strength will gradually increase, while the irritability and consequent fever will be proportionally diminished.

The medicinal treatment, we are told, depends much upon the character of the inflammatory fever. When the general circulation is inordinately increased, and when considerable pyrexia attends sub-acute inflammation, sedative medicines, such as tartarized antimony and digitalis, are recommended, though upon what principle it is difficult to imagine; for every one must, I think, perceive, if it be right, in the dietetic treatment of the constitution, to increase the general circulation, by the fearless administration of milk, beer, wine and water, eggs, and good broth, that it cannot at the same time be proper, in the medicinal treatment, to lower the vascular action by means of tartarized antimony and digitalis. But it happens that this treatment can seldom be put into execution; for when emetic tartar is given in doses sufficiently large to produce a sedative effect, it never fails, at the same time, to cause severe nausea; so that when a patient is under the influence of that medicine, his stomach, which must be in a very unfit state to receive eggs and broth, will necessarily rebel against those good things, and either refuse them admittance, or eject them soon after their entrance. As far, therefore, as regards the constitution, it must, I think, be plain that the treatment recommended for it by Mr. Searle is inconsistent, and often impracticable.

Under the head of the treatment of the local disease, we are told that it is sometimes necessary to depress and sometimes to raise the circulation. The vascular action is to be depressed by means of tartarized antimony, when inflammation has been caused by excitement of the general circulation; but this is nothing more than the practice which is recommended for the treatment of the constitution. The vascular action is to be raised when inflammation of an internal organ has been brought on by any considerable depression of the circulation, as when the surface and extremities of the body have been exposed for several hours to wet and cold. In a case of this kind, sudorifics, warm baths, flannel clothing, and whatever excites the general circulation, are recommended; and when the feet remain cold, and the circulation continues languid, blisters or sinapisms to the patient's insteps, and diffusible stimulants, become, Mr. Searle states, indispensable, in order to raise the general circulation “to the level of that in the inflamed organ,”

whereby he thinks that the superabundant quantity of blood which exists in the diseased part will be reduced.

But let us suppose the internal organ which is affected to be the intestinal tube. What, in a case of this kind, would be the effect of Mr. Searle's stimulating plan of treatment, provided it could be followed, which will seldom be the case, because, in acute enteritis, the stomach is frequently so irritable that it ejects every thing? But admitting that diffusible stimulants could in such a case be taken by the patient, and kept in the stomach, what, I ask, would be their immediate effect? In consequence of the general circulation being raised, the vascular action in the extremities and outer surface of the body would be increased, and, at the same time, and in the same ratio, the action of the larger vessels in the diseased part; for I do not agree with Mr. Searle in opinion, that, by increasing the general circulation, we draw the blood, as it were, from the diseased over-loaded organ into the extremities and outer surface of the body. No; when the general circulation is increased, the blood is propelled, with increased force, throughout the whole of the body, and, therefore, as diffusible stimulants are general stimulants, and exert no specific local influence, to whatever extent the circulation may in any one part of the body be raised through their agency, it will to the same extent be raised in the larger vessels of the diseased organ, *above the state* in which it was before these medicines were administered; so that if this view be correct, it clearly follows, that to give diffusible stimulants in a case like the one now under consideration, would only be to add fuel to a raging flame.

But if we were to adopt a different practice: if, instead of giving diffusible stimulants, we were to open a vein, and to take away a large quantity of blood, and if the pulse, soon after this, were to rise and become fuller, as it generally does after bleeding in enteritis, we should in this way not only increase the vascular action in the extremities and outer surface of the body, but, at the same time, lessen the determination to the bowels, by removing from the body a considerable quantity of that very fluid, the presence of which, in the diseased part, is the immediate cause of the inflammation. This, which is the practice of the present day, is a practice founded upon reason; it is a practice which experience has led us to adopt; and it is a practice which, notwithstanding Mr. Searle's objections, will continue to be followed by all judicious physicians so long as the nature of inflammation remains unchanged.

But Mr. Searle strenuously opposes the antiphlogistic plan of treatment, on the ground that it consists of lowering measures; and yet he says that the circulation ought sometimes to be lowered, according to the primary cause which has given rise to the inflammation. What is this but antiphlogistic treatment? Surely, when we lower the circulation, we do so by antiphlogistic means,—by means which, we are told, are opposed to Mr. Searle's views, and which, he says, often destroy life when the disease would not. But, if inflammation ought always to be treated according to its primary cause, when that cause can be discovered, and if the primary causes of inflammation be numerous, and some even of *opposite* nature, as Mr. Searle admits, it follows that the treatment must vary according to the primary cause, and, therefore, that antiphlogistic measures cannot always be improper. For instance, when an inflammatory disease has been brought on by a cause the very opposite to one which would excite an inflammation, for the removal of which stimulants are requisite, the antiphlogistic or lowering treatment, in such a case, must, for obvious reasons, be the only treatment which could be had recourse to with any thing like a rational prospect of success.

But Mr. Searle will not admit this. He seems to have a strange antipathy to the words antiphlogistic treatment, and only to the *words*; for he admits, as has been shown, the principle upon which that plan of treatment is founded, and yet, when it is *called* antiphlogistic, his language respecting it, from the beginning to the end of his paper, is the language of condemnation; indeed he goes so far as to say, that "inflammation, like fever, is a bugbear;" that the strict antiphlogistic system of treatment is always injurious, and always of fatal tendency; and that its measures are tenfold more terrific than the disease itself.

Will it be believed that this is the language of a British surgeon in the year 1836? Surely some sort of a professional mania has broken out in the land. One man tells us that fractured thigh-bones may be cured, in an amazingly short space of time, by merely placing the patients in an easy position on a bed, and leaving them to nature and a pillow; another, that a few infinitesimal doses of common sulphur, each dose not being larger than a *billionth* part of a grain, will work wonders in removing some diseases over which no other kind of medicine would have any power; and a third soberly and seriously states, that the antiphlogistic plan of treatment, in acute inflammatory diseases,

ought to be carefully avoided—that if it were, for the first time, proposed for the consideration of the profession, in this enlightened age, it would be treated with deserved contempt—and that if Hippocrates were to rise up from his grave, and to hear of nothing but the antiphlogistic treatment, he would offer a woful lament for mankind, because twenty-two centuries have produced, in the chief department of medical practice, nothing better than a rule without a reason. Surely, after this, no one will doubt that some such malady as the above-mentioned is spreading amongst us, and that if it continue, it may be attended with direful consequences.

I should not, however, have taken any notice of Mr. Searle's opinion respecting the treatment of inflammatory diseases, had his paper not been published in a journal which is pretty extensively circulated, particularly among the junior members of the profession; but, seeing that it holds a conspicuous place in the *Lancet*, and fearing, on that account, that some may suppose the stimulating part of Mr. Searle's practice to be approved of by the conductors of that work, which perhaps is the case, I consider it to be my duty to lift up my voice against it. If the above observations should act as a caveat, and be instrumental in causing any of my young professional brethren to pause and think before they adopt a practice which every man of experience must know to be fraught with danger, the object which I have in view, in forwarding this letter for publication in your truly excellent journal, will be accomplished.—I have the honour to be, sir,

Your constant reader,

And most obedient servant,

INVESTIGATOR.

London, Oct. 17, 1836.

PARISH SURGEONS AND POOR LAW UNIONS.

To the Editor of the Medical Gazette.

SIR,

WILL you permit me, through the medium of your GAZETTE, to make a few observations on the following advertisement, which has lately appeared in the *Northampton Mercury*?

“LEIGHTON BUZZARD UNION.

“To Medical Gentlemen.

“The Board of Guardians are desirous of receiving applications from medical gentlemen, duly qualified, who may wish to

fill the situation of medical officer of this Union.

“The Union consists of the following parishes:—Leighton Buzzard, Billington, Egginton, Heath and Reach, and Stanbridge, in Beds, — and Edlesborough, Ivinghoe, Slapton, Grove, Wing, Linslade, Soulbury, Cheddington, Martmore, and Stoke Hammond, in Bucks; and comprises a population of 11,800 persons.

“The gentleman appointed will be required to devote his whole time and attention to the duties of his situation, which will comprise, amongst other things, due and punctual attendance in all medical, surgical, and midwifery cases, and vaccination for all paupers; and he will provide, at his own cost, all medicine, drugs, and medical and surgical requisites, &c., trusses excepted. He will be required to enter on his duties on the 1st of December next, and to reside in the workhouse at Leighton Buzzard, where apartments (unfurnished) and stable-room will be provided for his accommodation.

“The salary will be 200*l.* a year.

“Testimonials of qualification, character, &c., accompanied by a letter, stating the age of the applicant, and whether he be married or single, to be sent, free of postage, addressed to the Clerk to the Board of Guardians, Leighton Buzzard, on or before the 20th October, instant.

“The Guardians, at the meeting of the Board, on the following day, propose to select from the gentlemen sending in testimonials, three applicants, who, on receiving an intimation to that effect, will be expected to attend in person at the next meeting, when it is intended that the appointment shall take place.

“The Board, however, do not pledge themselves to elect any applicant, unless fully satisfied of his eligibility.

“Leighton Buzzard, Beds.
Oct. 1, 1836.”

In the first place, I cannot but observe how firmly resolved these gentlemen of the Board of Guardians are, to appoint no one as their surgeon who is not duly qualified for the office—will devote his whole time to its numerous duties—and can produce testimonials favourable to his character.

Now all this is exceedingly proper—no one can dispute it; but supposing any surgeon, possessing the requisite qualifications, were capable of fulfilling the duties of the situation (which I am confident the physical powers of no one man in existence are equal to), how is he to be remunerated?

“The salary will be 200*l.* a year.” How very inadequate a sum for providing medical and surgical attendance—medicines of all descriptions, and attendance on mid-

wifery cases, for a population of 11,800 persons, extended through fifteen country parishes! I am not acquainted with Leighton Buzzard, or its neighbourhood; but I know well what a country practice is, having been engaged in one for the last five-and-twenty years. Why, sir, the midwifery alone, extended over so wide a district, would be far more than any one person could accomplish: the number of cases occurring annually would probably be from twenty-seven to thirty for every thousand of the population. Can any person, having the slightest knowledge of the frequent, vexatious, though unavoidable, delays incident to midwifery practice, imagine it possible for any one individual to attend annually between 300 and 400 accouchements, scattered through fifteen country parishes?—an average of nearly one case every day! I can picture to myself the poor fellow, after riding hard through a dreary winter's day, returning, not to a quiet comfortable home and a happy domestic circle, but to his solitary apartment in a parish workhouse: there he sits in solitude, but not in quiet; for constantly is he assailed by the ceaseless din of its clamorous inmates;—in despair he retires to his couch, but scarcely has he stretched his weary limbs, and closed his eyes in slumber, ere a loud knocking at the outer gate, accompanied by an impatient shout, rouses him from a momentary oblivion: again must he mount his already jaded steed—again must he brave the inclemencies of a winter's night, and plunge through the mud of numerous intricate lanes, the only path to some wretched cottage four or five miles distant. Here he is compelled to wait the event of a tedious case, not unattended with hazard; seated by the side of a smoky fire, he rests his head against a pillow fastened to the wall by a fork to prevent its falling, and endeavours to procure a little sleep. Morning at length arrives, but his patient must not be left: anxiously he considers how he shall get through the various duties of the coming day. In the midst of his deliberations a hasty messenger, mounted on a panting cart-horse, demands his immediate attendance in an opposite part of the Union. What can he do?—how is he to proceed? His misery is complete;—no, far otherwise: before he has time to reply to the last messenger, another arrives with the intelligence that a man has been run over by a waggon, that his thigh is broken, and that he lies bleeding at a public-house about three miles distant. Where shall he look for assistance? The neighbouring practitioners will not afford it; if they do, the Board of Guardians will not pay them for their exertions, however urgent the case

may be: he has taken the union, and must abide the consequences. Of this I have myself very lately had proof. But do not mistake me; I have not taken an union, nor will I take one. The case I allude to is briefly as follows:—A neighbouring surgeon, having a pauper patient in a very dangerous state, sent for me to consult with him on the propriety of an operation. I attended, at a distance of about five miles from my own home; the operation was decided on, and immediately performed. The Board of Guardians referred the case to the Poor-Law Commissioners in London, who immediately refused to sanction any payment whatever.

But supposing it possible for any one man to accomplish the duties required, how very paltry the remuneration! Two hundred pounds per annum, for a man who has gone through the whole routine of his medical education, and, by passing his examinations, proved himself qualified for practice! I hope the various lecturers in London, when they give the farewell address to their pupils at the close of their several courses of lectures, will not fail to set forth, in proper colours, the various benefits arising from a Poor-Law Union. I hope the President of the Royal College of Surgeons, when the oath in which they swear to promote the dignity and welfare of the College is administered to the candidates for the diploma, will not fail to inform him, that, if they conduct themselves fairly and honourably in the practice of their profession, they may, in due time, expect to be promoted to the enviable situation of an Union surgeon; that should they be fortunate enough to obtain the Leighton Buzzard appointment, after they are completely worn out with its arduous duties, they may probably be permitted an asylum in the workhouse; and, after a life of ceaseless toil, finally close their eyes to this world, stretched on a miserable pallet in a ward crowded with paupers.

But to resume: the poor ought to be attended, during any illness with which they may be afflicted, by properly educated and duly authorized practitioners, members of the Royal College of Surgeons, at a good and sufficient salary, who should not be compelled to undertake an immense district, and forego all the advantages of private practice. The districts should in all cases be small, and manageable; if to the exclusion of private business, the salary should be much larger than where private practice is permitted. But, in each instance, the surgeon should be allowed, in urgent cases, to call in the assistance of a neighbouring practitioner, who should be properly remunerated for his services.

I have often wished that parish surgeons were appointed and paid by the government. Why not have government surgeons to parishes, as well as to ships and to regiments? How very differently, and how very easily, would the business be managed. Take the Leighton Buzzard Union, with its population of 11,800 persons, for instance. The Guardians propose to elect one surgeon, with a salary of 200*l.* a year, and apartments in the Work-house.

Now, sir, let us look to the navy, and see how the affair is managed in that service. The crew of a first-rate ship of war, including officers, is 900 persons; therefore, the crews of thirteen first-rate ships would be 11,700 persons, 100 less than the Leighton Buzzard Union. All medicines are provided by government. Every ship is allowed one surgeon and three assistant-surgeons, all of whom are duly qualified for naval practice;—and how are these gentlemen paid? The ship is their home, and they have the ship's allowance of provisions: if they think proper to keep a more luxurious table, they are at liberty so to do. The net annual pay of a surgeon is 159*l.* 9*s.* 4*d.* in all rates: any increase of pay depends upon length of service, and not on the size of the ship. The net annual pay of an assistant surgeon is 119*l.* 12*s.* in all rates; consequently—

	£	s.	d.
The annual pay of 13 surgeons will be	2073	1	4
The annual pay of 39 assistant-surgeons (three to each ship)	4664	8	0
Total annual pay of the medical officers of 13 first rate ships of war, containing 100 individuals less than the Leighton Buzzard Union, for which 200 <i>l.</i> per annum is offered	6737	9	4

I am not so well acquainted with the pay and allowances of the army surgeons and assistants; but I have reason to believe that the difference is not great: I know there is an allowance for the keep of a horse.—I am, sir,

Your obedient servant,
AN OLD NAVY SURGEON.

TETANUS.

NOTE FROM MR. CURLING.

To the Editor of the Medical Gazette.

SIR,
In the notice of my work on Tetanus in your last number, you refer to a case men-

tioned on the authority of Wepfer, in which it is stated, both in my Essay and in the GAZETTE, the disease proved fatal in *three* minutes. This is a misprint. It should have been *thirty* minutes, and stands corrected thus in the "Corrigenda." As the error makes a considerable difference in the case, you will oblige me by noticing it.—I am, sir,

Your obedient servant.
T. B. CURLING.

Mount Place, London Hospital,
October 31, 1836.

PATHOLOGY OF EPILEPSY.

DR. SEYMOUR'S LECTURE.

To the Editor of the Medical Gazette.

SIR,
YOUR GAZETTE of Saturday last contains a report of a clinical lecture by Dr. Seymour, in which it is stated that the Wenzels published a work some years ago, in which 30 cases of that disease are mentioned, and "in every one of these there was more or less disease of the *cerbellum*." Dr. John Sims* pointed out an error in this statement, and ascribed the mistake to the circumstance of the word "*hirnanhang*" (pituitary gland), having been incorrectly translated "*cervelet*," in a French version of Wenzel's work, with which English writers were better acquainted than with the original.

If Dr. Sims' remarks were correct (and I am not aware that they have been contradicted), it is desirable that the error should not be propagated by so respectable an authority as Dr. Seymour's.

I am, sir,
Your obedient servant,
W. R. BERNARD.

[Cheltenham, Nov. 1, 1836.]

CASE OF
EXTENSIVE AND DEEP-SEATED
INJURY OF THE BRAIN,

Unattended by any disturbance of the intellect,
and terminating favourably.

By JAMES COUPER, JUN. M. D.
Of New Castle, Delaware.

On the 13th of September, 1835, at 10 o'clock in the morning, a son of Mr. Allen of this neighbourhood, three and a half years old, of full size and perfect health, climbed to the top of a fence four feet

* See MEDICAL GAZETTE, Dec. 18, 1836.

eight inches in height, and when there lost his balance, and fell headlong on the opposite side. On that side of the fence there happened to be a pile of weather-boards, which had been taken from an old building. One of them rested on the ground, and extended to the spot upon which he fell. It was so firmly fixed by the weight of boards above it, as to be incapable of yielding to the impulse of a body falling on it, and through the end of it the sharp extremity of a wrought nail projected. In falling, the head of the child struck upon this nail. Its point entered the right parietal bone, just behind the central point of the right half of the coronal suture, and at the distance of half an inch from it. Its direction was, from the point of entrance, towards the centre of the base of the brain, and the part of it which entered the skull measured two inches and a quarter. After the head had been driven close up to the surface of the board by the perpendicular force of the fall, the child fell over on his right side, thus causing the point of the nail to describe a segment of a circle within the substance of the brain. The accident was first observed by a girl belonging to the family, who ran to the assistance of the child, and made several ineffectual efforts to relieve him by lifting up his body. Having failed in her attempts, she called to her aid a young man, who at first made like trials to release him, by raising his body from the ground. Defeated in these, he at last succeeded in extricating the boy from his distressed situation, by interlocking the fingers of both his hands beneath the head, and forcibly raising it off from the board. Upon the extraction of the nail, small portions of brain were found adhering to it, and other pieces afterwards came away from the wound. But little blood was lost; it amounted, perhaps, to two fluid ounces, and came principally from a minute arterial twig belonging to the scalp. When I first saw the patient, which was within an hour from the time of the accident, he had fallen asleep, but was readily aroused by my efforts to clear away the blood from the wound, and struggled resolutely to escape from them. During the afternoon of that day, he vomited freely several times. At ten o'clock at night, he was suddenly seized with total loss of power over the left side, but without any corresponding loss of sensation, or any paralytic affection of the tongue. His speech, both then and afterwards, was perfectly natural, as were also his eyes and the general expression of his countenance. Distinct attempts were made by the system to set up inflammatory action within the cranium on the second, fourth, fifth, and seventh days after the injury, but these

were readily defeated by prompt and efficient depletory measures. A slight discharge continued to flow from the wound for about a week, and then ceased entirely. The paralysis has passed off regularly, but slowly. At this time (five months from the date of the accident), although the child runs about as usual, and exercises constantly and very freely without difficulty, there remains a slight general weakness of the arm, with a degree of defect in the power of the flexor and adductor muscles of the thigh of the affected side. The treatment of this case, in which I was aided in consultation by Dr. Baker, of Wilmington, consisted in the diligent use of free general and local depletion, together with those other measures by which inflammation of the brain may be prevented or removed. The preceding case appears to me to be interesting—

1. On account of the depth and extent to which the brain must have been broken up by the nail in its entrance, and its subsequent movements within the cranium, produced by the various ill-directed efforts to release the child.

2. From the fact that paralysis of the opposite side did not come on as an *immediate*, but *remote* effect of such serious injury to the brain, occurring at the end of twelve hours from the time of the accident, and that *suddenly*.

3. As exhibiting an instance of recovery after extensive *deep-seated* damage to the brain, and especially as proving that such important mischief within the skull does not necessarily impair the intellectual powers. No aberration of mind whatever was observed during the whole course of the case, although it was carefully watched with particular reference to this point*.

MR. WALFORD.

If the Editor of the Lancet is to be believed, a person named Walford has intimated to him, that he (the said Mr. Walford) was not privy to certain editorial articles which have recently appeared in this journal. For the information of all whom it may concern, we beg to state that no person of that name ever was, in any way, directly or indirectly, connected with the MEDICAL GAZETTE, and that the circumstance alluded to, if it ever occurred, must either have been intended as a hoax upon Mr. Wakley, or be the result of some incomprehensible impertinence on the part of his correspondent.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE VII.

Further Remarks on the Identity of Living Persons—Extraordinary case of alleged Abduction and contested Identity—Some recent Cases. Identity of Persons found Dead—Supposed remains of Hampden and Milton—The head of Charles I. identified—Identity of the victim essential in prosecutions for Murder—Remarkable instances of identification which have occurred in England and France—Inquiries relative to changing the colour of the Hair for the purpose of confounding identity—Hints for detection—Practical rules for the investigation of cases of doubtful identity.

I HAVE given some instances of identity being mistaken in criminal prosecutions; eye-witnesses swearing positively to the identity of a wrong party. I shall add one example more, from the extraordinary case of Mary Squires, which occupied so much of public attention about the middle of the last century, and which to this hour has not been satisfactorily cleared up.

Extraordinary case of contested identity.—Mary Squires was an old gipsy-woman, who might have lived unnoticed, and died without remembrance, had not a prosecution for robbery, followed by sentence of death, fixed the public eye upon her. The circumstances of the case excited inquiry, and, according as prejudice or party operated, the convict became alternately an object of detestation, pity, or contempt. It appeared by the declaration on oath of Elizabeth Canning, a girl about eighteen years of age, that on the night of new-year's day, 1753, she was returning to her

master's house, in Aldermanbury, from the neighbourhood of Rosemary-lane, when she was stopped, near Bethlem wall, Moorfields, by two men, who robbed her of her gown, apron, hat, and half a guinea, tied her hands behind her, and, on her struggling, gave her a violent blow on the temple, accompanied with oaths and execrations. She was then dragged to the house of one Mother Wells, at Enfield-Wash, where she saw Mary Squires. Squires made her overtures, as Canning understood her, to become a prostitute; and, upon her refusal, ripped up her stays, which she took from her, and, after many threats, thrust her into a back room, or hay-loft, where she was confined for twenty-eight days, without fire, or any kind of sustenance, except some pieces of bread, amounting to about a quartern loaf altogether, about a gallon of water in a pitcher, and a small minced pie which she accidentally had in her pocket.

During the whole of this time, Canning further declared that no human creature visited her. The bread and water being exhausted, she broke down a window-shutter, which was nailed, got out of the window on a sort of pent-house, and thence jumped to the ground, nine or ten feet below, according to her description. She reached home, by walking, as fast as her weak condition permitted.

The case became known, and immediately excited the sympathy and indignation of the public. A subscription was got up for the young woman. Squires and Wells were taken into custody, tried at the Old Bailey, and sentence of death passed on the former.

But Sir Crisp Gascoyne, the Lord Mayor, perceived that there were many contradictory points in Canning's evidence. Her description of the loft in which she was confined did not exactly tally with the room in Wells's house. A girl, too, one Vertue Hall, who had been a principal witness for the prosecution, retracted her

evidence, "having been threatened and frightened into what she had sworn." This girl had, in the first instance, corroborated the statement of Canning relative to the conversation at Enfield with Squires, and the ripping of the stays. A memorial was presented to the King, and the convict was respited for a few weeks. She ultimately received a free pardon, upon the law officers of the crown declaring that the weight of evidence was in her favour.

A re-action now took place; for if Squires was not guilty, Canning could not be innocent: the latter was accordingly indicted for perjury. Her trial, which did not come on for nearly twelve months after that of Squires, occupied five days: the witnesses were numerous, and their testimony of a very intricate and contradictory nature.

The question of Identity was the one on which the proceedings chiefly turned. Could Canning, and could a host of other persons, be mistaken in the appearance of Squires? The old woman had features of the most remarkable description. When the constable went with the warrant to apprehend her, she said to Canning, on being charged with robbing her of her stays,—“Do you say I robbed you? Look at me: if you have once seen my face, you must remember it, for God Almighty never made such another!”

It is said that when this part of the evidence was given in court, every eye was fixed on the old woman, whose countenance exhibited an assemblage of the most uncommon, and diabolically hideous features.

Yet thirty-six witnesses swore one way, and twenty-six another, as to seeing her at certain places about the same time. It appeared, according to one train of evidence, that the old gipsy was at Abbotsbury in Dorsetshire, from the 1st of January to the 9th; that she was in various places in Dorsetshire, Wiltshire, Hampshire, &c., from that time to the 18th; and that she did not arrive at the house of Mother Wells till the 23d. On the other hand, it was proved, or attempted to be proved, that she was, during this very time, seen nearly every day in the neighbourhood of Enfield.

The only *medical* evidence produced was that of a physician and an apothecary, who deposed to the languid and reduced state of Elizabeth Canning on her return to her mother's, and that she appeared like one who had suffered extreme hunger, thirst, and cold; but they acknowledged that a person might be as she was from other causes.

There were, however, several circumstances in the case that would have admitted of medico-legal elucidation. In a

physical or physiological point of view, it is highly improbable that the girl could have subsisted for eight-and-twenty days on a quartern loaf and a gallon of water; or, at all events, if life remained, the sufferer should have been nearly exhausted from famine; her person should have exhibited striking proofs of starvation from cold and hunger: yet there is no reason to believe that such appearances were remarkable in the alleged sufferer.

Other minor but not less important points might have engaged the attention of the medical jurist. If Canning had been confined so closely in a hay-loft for so long a time, the natural excretions might have been referred to in proof; and the catamenia, also, would probably have left their traces. No notice, however, seems to have been bestowed on these things.

It has been already mentioned that Canning's account of the place of her incarceration was incorrect in certain particulars: it was, in fact, such an account as might have been trumped up from the description of somebody who had seen the place; but this was not all: some damning facts against this part of her evidence came out on the trial. A poor man, named Fortune Natus, proved that he and his wife slept in the room in which Canning swore she was confined, during the whole of that month, and for five or six weeks before. This testimony was also corroborated by Ezra Whiffin, a neighbour of Mother Wells, who being in want of a sign-board, and hearing that she had one to dispose of, called to see it, and accompanied Wells into the very room in question to seek for it. They there found it under some hay, which made part of the bed on which the wife of Natus was actually lying at the time—namely, on the 18th of January. It was not possible that Canning could have been in the room, or she must have been seen, and would probably have called for help. She had sworn, besides, that no person of any description had entered the room during the whole of her confinement.

I omit a great many other discrepancies and contradictions which came out in evidence. There were not less, it is said, than 120 witnesses examined altogether. The jury brought in a verdict of “wilful and corrupt perjury;” and the sentence was “transportation for seven years.”

Yet, strange to say, many people still insisted on the innocence of Elizabeth Canning: the newspapers and periodicals of the time were filled with discussions on the subject. Fielding, the novelist, who was also a magistrate, wrote a pamphlet in Canning's favour; but he was replied

to with critical severity by Dr. (Sir John) Hill. To conclude the story, Canning was transported to New England, according to her sentence: there she married advantageously, and one of her original supporters left her a legacy of 500*l*. I may add, that before her departure, wishing doubtless to have the last word, she published a declaration in these terms:—"I declare in the most serious manner, that I am fully persuaded, and well assured, that Mary Squires was the person who robbed me, and that the house of Susannah Wells was the place in which I was confined for twenty-eight days!" It certainly has never been explained where she was during the twenty-eight days, if not in Mother Wells's hay-loft.

Such were the leading facts of a transaction which excited as much interest at the period as the *affaire La Roncière* has latterly done in France. In both, the testimony of a young female formed the chief ground of accusation against a prisoner; in both there has been room for medico-legal research; but the main features of the charge have been very different in each, as I may hereafter, in alluding more particularly to the *La Roncière* cause, have occasion to show.

Identity of a child.—The question of a child's identity was raised in a recent trial at Cambridge, for an assault. The parties were *Wagstaff v. Bruyere*. The prosecutrix (Miss Wagstaff) swore that she was the mother of a child which was carried away from her forcibly by Mr. Bruyere, and some police officers. Mr. Bruyere (brother-in-law of prosecutrix) proved that it was his wife's child which he took away, and that it was seven months younger than Miss Wagstaff's. A medical witness gave some important testimony. He had attended Mrs. Bruyere professionally in all her confinements, and he swore to the identity of the disputed child, "bringing forward some of the *most convincing reasons*." What these reasons were I have not been able to learn; but it is probable they were certain personal marks and peculiarities. Much stress was laid upon the colour of the hair, the colour of the eyes, and the growth of the child. I need not more fully allude to this remarkable trial, of which you will find a good report in the *Times*, July 29, 1836; but I have no doubt that, had it occurred in France, it would have obtained a place among the *Causés célèbres*.

In another trial, for murder and robbery, which took place lately at the Exeter Summer Assizes, the identity of one of the prisoners was questioned: and the fact of his wanting one or two of the front teeth was particularly dwelt on by some of the witnesses.

But it may probably be said, that in

most cases of this kind, the evidence of ordinary witnesses is as much to the purpose as that of medical men. There may be some force in the observation, though in most of the examples which I have quoted, medical evidence either was, or might have been, given with much advantage; but at all events, supposing that professional testimony may not greatly avail in identifying living persons, the case is different when we have to examine the dead: and this brings me to the second division of my subject—

Identity of the Dead,

Essentially medico-legal.—In investigations respecting the identity of individuals found dead, especially where the remains may be much decomposed, or reduced to a mere skeleton, medical men are obviously the fittest persons to be entrusted with such a task. Their familiarity with the appearances of the human subject, acquired during their anatomical and pathological studies, and their habit of observing the features and general aspect of the dying and the dead, render them the most capable of appreciating the alterations which dissolution and external influences usually produce.

Of the changes wrought in the human body during the progress of putrefaction under various circumstances, I shall hereafter have to treat with all the requisite detail. At present we shall confine ourselves to examples of the mode in which identity has been ascertained in doubtful cases, and conclude with some practical rules which may be beneficially employed by the medical jurist.

Remains of Hampden.—A curious inquiry was instituted in the year 1828, at Hampden Church, Buckinghamshire, by which, indeed, not exactly a medico-legal, but a medico-historical, point was to be determined. Hampden, the patriot, was known to be there buried: he had received a death-wound in the battle of Chalgrave Field, in 1643; but the nature of that wound, and the circumstances of his death, are variously related by historians. Lord Clarendon says he was shot in the shoulder with a brace of bullets, which broke the bone, and caused his death in three weeks; while another authority informs us that he died in the course of a few days, in consequence of the bursting of his pistol, which shattered his hand in a shocking manner. It was thought that a view of the body would settle the question; and a formal visit was made to the vaults in Hampden Church, for the purpose; but the result was not as favourable as might have been expected.

As there has been some controversy concerning the trustworthiness of the published reports of the examination, I

shall not enter into the details, referring you for the satisfaction of your curiosity on the subject to the Gentleman's Magazine for 1828. Thus much, however, relative to the disinterment, has been ascertained through the inquiries of Mr. Southey (I quote from his Letter touching Lord Nugent):—"that search was made, in the place mentioned, for the body of Hampden, and, as the persons present understood, at the instance of Lord Nugent [his Lordship was at the time engaged on his Memorials of Hampden]; that several coffins were inspected, but not opened, because either the date did not agree with that of Hampden's death, or the inscription bore a different name; that one coffin was at length found, which had neither date nor inscription, and this was opened, although, from its form, it appears to have been older than his time. Mr. Norris, a surgeon of Risborough, examined the body, which was that of a very lusty man, the head covered with rich auburn hair, reaching beneath the shoulders: it was in high preservation, except that one arm crumbled off, owing to the action of the air, which had made its way to that part through a crack in the coffin; but there had been no amputation, nor operation of any kind."

Remains of Charles the First.—The search for the remains of King Charles the First, at St. George's Chapel, Windsor, in the year 1813, was more successful. It was conducted by Sir Henry Hallford, in presence of the Prince Regent, and some members of the court. The particular vault in which the coffin was deposited had long remained unknown, though it was understood to be the one in which Henry the Eighth and one of his wives were laid. Accident led to its detection. A scroll, with name and date, served in some measure to authenticate the outer covering; but the examination of the head left not a doubt of the identity of the royal remains. Upon disengaging the face from the cere-cloth, which had been lined with an unctuous and resinous substance, apparently with a view to exclude the external air, the complexion of the skin was observed to be dark and discoloured. The forehead and temples had lost little or nothing of their muscular substance: the cartilage of the nose was gone; but the left eye, in the first moment of exposure, was open and full, though it vanished almost immediately; and the pointed beard, so characteristic of the period of the reign of King Charles, was perfect. The shape of the face was a long oval; many of the teeth remained; and the left ear, in consequence of the interposition of the unctuous matter between it and the cere-cloth, was found entire. The countenance, in short, notwithstanding its

disfigurement, bore a strong resemblance to the coins, the busts, and especially to

FIG. 15.

the pictures of Charles the First by Van-dyke. Finally, the fourth cervical vertebra was found divided transversely—the corresponding surfaces being smooth, betokening that they had been separated by a heavy sharp instrument. I quote these particulars from the interesting narrative lately published by Sir Henry Hallford.

Supposed remains of Milton.—When researches of this kind are attempted by incompetent persons, the most gross blunders are often committed. As an instance, I may mention a disinterment which took place some forty years ago, in this very neighbourhood. Milton was known to have been buried next his father, in the chancel of St. Giles's, Cripplegate. In August 1790, the spot where his body had been deposited was opened, and a corpse hastily supposed to be his was exposed to public view. But it was suspected by some, nay, asserted—nor has the assertion ever been disproved—that the disinterred corpse was that of a female. One gentleman (Mr. Capel Lofft), in censuring the "sordid mischief" committed on the occasion, and "the market made of the eagerness with which curiosity or admiration prompted persons to possess themselves of the supposed remains," tells us there was reason to believe that the said remains, so far from being Milton's, were "the bones of a person not of the same age or sex!"

Legal distinction.—When it is remembered that, consistently with our law, no man can be condemned for murder

unless the body or remains of his supposed victim be produced and identified, we must admit the deep importance of attending to this subject. Eugene Aram made it a part of his ingenious defence, that the skeleton which was found *fourteen years* after the supposed murder, was not proved to be Clarke's; so far from it, that it was not even shown to be a male skeleton; and he argued, that the bones produced might have been those of some hermit who had, in former times, inhabited the cave where they were discovered.

More satisfactory evidence of identity is required in modern trials. Several medico legal disinterments might be referred to in proof of the fact. In the case of Maria Martin, who was murdered by Corder, evidence of the identity of the victim was obtained by exhuming her body after it had lain buried in a barn for eleven months. Mr. Lawton, the surgeon, gave evidence at the trial. He described the appearances, by which the nature of her death was ascertained. The head of Maria Martin was identified chiefly by the absence of one or two teeth from the upper and lower jaw. Certain observations also, which were made on the state of the lungs, were important: there were adhesions of the pleura, and other marks, by which it appeared that the deceased had had cough and pain of the chest not long before death—which was precisely the case with this unfortunate young woman.

I have already mentioned the case of the late Marchioness of Salisbury, whose remains were identified by the jaw-bone having certain appendages for artificial teeth. Another instance of a similar kind may be worth quoting. Four medical students were prosecuted at Edinburgh some years since, for exhuming the body of a lady. It was necessary to identify the remains, and much difficulty in this respect arose from the very contradictory evidence of the medical witnesses as to certain appearances connected with the ovaries: the point, however, was eventually determined by a dentist, who produced a cast of the gums which he had taken before death.

In the year 1814, Dupuytren identified the person of a murdered man, chiefly by observing a coxo-femoral malformation under which the deceased must have laboured. The description of the parts, as given in the official report, (*Annales d'Hygiène*, vol. i.) is beautifully clear; but the following is perhaps all that properly belongs to our present subject; it constitutes the first part of the summing up, or *résumé* of the report:—“1. The body submitted to us was that of a man between 36 and 40 years of age. 2. He must have had, in infancy, disease

of the two articulations of the thighs with the pelvis. And 3. This disease, though of old standing, and cured, must have left a remarkable deformity about the lower part of the trunk; and the individual, in his movements of progression, must have experienced difficulties—probably lameness—certainly an unpleasant balancing of the body on the lower limbs.” M. Dupuytren then proceeds to shew that there was a difference in the length of the limbs, and that the deceased must have walked chiefly on the toes of his right foot.

In another remarkable case investigated by MM. Laurent, Noble, and Vitry, at Versailles, in the year 1828, the remains of a man who had been murdered, and had lain buried in a cellar for about three years, were identified by noting an analogous malformation, which must have produced a certain degree of lameness. After stating the sex, age, stature, and other particulars relating to the skeleton, the reporters say in their conclusions:—“From the structure of the bones of the pelvis, the depression of the fifth lumbar vertebra, the curvature of the bones of the legs, and more particularly of those of the left side, which is six lines shorter than the right, the individual must have had rachitis in his infancy; and if he did not actually halt, he must at least have leaned considerably in his gait towards the left side.”

A very singular case was investigated at Paris two or three years ago, one in which proof of identity was successfully deduced from the relics of a female *eleven years* buried. I have already alluded to some of the circumstances; but they are altogether so striking, and so illustrative of the subject under consideration, that I shall read for you an abstract of the official report drawn up by Orfila, Chevallier, Baruel, and Boys de Loury, the medico-legal examiners engaged in the investigation:—

In the year 1821, a widow lady, of the name of Houet, residing in the city of Paris, disappeared; and certain persons, Bastien, Robert, and Robert's wife, who had taken the house, No. 81, Rue de Vaugirard, were suspected of having made away with her. A judicial inquiry was pending for some time, in the Court of Assize; but the accused, for want of evidence, had been set at liberty. Not long ago, however, some information was obtained touching a body said to have been buried for about eleven years in a particular garden. An investigation was accordingly set on foot; and by dint of patient and ably-directed research, such satisfactory evidence was procured of the identity of the remains, and of the manner of the death, that the prisoners were convicted, and punished.

The first part of the inquiry—the juridical exhumation—was conducted by M. Boys de Loury. After excavating different parts of the garden for about five hours, one of the workmen hit upon a hollowed spot, in which there were bones. The greatest care was taken to uncover them with the least possible disturbance; they were evidently those of a human body, reduced almost to a perfect skeleton. A drawing was made of the parts *in situ*. The figure reposed on the left side; the head was bent forward on the neck; the vertebral column was curved; the right fore-arm was raised, so that the bones of the hand nearly touched those of the face. The pelvis was turned obliquely upwards, resting on the left haunch. The thigh-bones were raised considerably, and the legs were crossed beneath them. The colour of the remains generally was between an ochre and a brown; and when the earthy matter was removed from some of the long bones, the uncovered parts were found to be of a deep red colour.

The grave was four feet deep, funnel-shaped, measuring five feet and a half in length at its upper part, but at the bottom only two and a half: its greatest breadth was about two feet. Some lime-stone had been placed over the body, so as to form a sort of vault. Having made these general observations, the particular parts were next examined. The skull was small and lengthy in its shape: it seemed, by the way, from the position of the head, that the body had been thrown into the grave head foremost. The parietal bones were very yielding: the sutures were well knit; the teeth white, and had been used with care: three molars were wanting, and one of the incisors was carious. A small quantity of light-coloured or ruddy hair was found, having some grey mixed with it.

The state of the neck was particularly striking. The third, fourth, fifth, and sixth cervical vertebræ, as well as the right clavicle, were held together by a blackish mass, in the composition of which there could not be recognized any tissue. *This mass was surrounded at its lower part by several twists of a cord two lines in diameter; the cord was in a very decayed condition, and no knot could be found upon it.* Minute attention was subsequently given to this *pièce de conviction*, and the obvious inference, that the deceased had been *strangled*, was fully borne out by all the direct and collateral circumstances.

Among the bones of the left hand was found a gold ring, of small diameter, carved in *facettes*; and several small well-formed finger-nails were also discovered. The pelvis, from its shape and proportions, could only be that of a woman. Some portion of cloth, probably part of a stocking, was found near the legs; but

upon exposure to the air, it rapidly crumbled to dust.

I need not enter into a more minute detail of the several parts found. Other reporters, MM. Orfila, Marc, Barruel, and Chevallier, were afterwards added to M. Boys de Loury; and three or four elaborate documents were drawn up, of the first of which I shall read the *résumé*:—

“From the preceding facts, we feel ourselves justified in concluding,

“1. That these bones are those of a *human skeleton*.

“2. That the skeleton is that of a *female*.

“3. That this female had attained the age of from 60 to 70.

“4. That her stature was about 4 feet 8 or 9 inches (nearly 5 feet Eng.)

“5. That the hair of the female, which was of a bright blond colour in youth, was mixed with grey at the time of her death.

“6. That the hands were small.

“7. That during life, the bones had never suffered any injury.

“8. That this woman died of strangulation, and that the act was, to all appearance, homicidal; and

“9. That the body must have lain for several years in the earth.”

A very ample report follows, stating the processes which were adopted for analyzing chemically the various debris about the body. Thus the earth at the bottom of the grave was examined, as were also certain concretions which were taken to be biliary calculi, and the softened masses in the neighbourhood of the pelvis: but nothing very important was detected in this search.

Justice was satisfied. The prisoners, who had been long suspected, were brought to trial and condemned. They were sentenced to forced labour for the remainder of their lives.

Inquiries respecting the Hair.—I am reminded by the remark in the report just quoted, respecting the colour of the hair, that there have been some special inquiries made by Orfila and others on this subject, which are exceedingly interesting, in a medico-legal point of view. Circumstances occurred in Paris, a few years since, which rendered it necessary to inquire whether a man who was suspected of having committed a murder, could have changed the colour of his hair in a very extraordinary manner, in a short time. Certain witnesses deposed to having seen him in Paris, at two in the afternoon, with black hair; while others declared that they saw him at Versailles, with fair hair, at five or six o'clock the same evening. The man's hair was naturally jet black, and it does not appear that he wore a wig. The question, in consequence, proposed by the

law authorities to M. Orfila was, whether black hair could be dyed fair? Michalon, one of the first hair-dressers in the French metropolis, who was also consulted, gave his opinion that it was impossible; but M. Orfila stated that it was not only possible, but had been effected twenty-six years before, by Vauquelin, by means of chlorine.

The question, however, as M. Devergie observes, was not sufficiently definite. It should not have been simply whether the thing was possible, but whether, within a given time—say a few hours—hair could be changed from black to fair?—for no small part of the difficulty consisted in the journey to Versailles, in addition to the process employed, and all within three or four hours. Repeated trials made since by experienced hands seem to indicate it as an impossibility.

Means of darkening the hair.—It is well known that there are various methods in use for altering the colour of the hair: in general the object is to change red or sandy hair to a darker hue, to brown or black. Preparations of lead, silver, and bismuth, are employed for the purpose, lime or ammonia being first used to remove the fatty matter of the hair; and a very common agent is a mixture or compound of lime and oxide of lead, called plumbite of lime, of the mode of using which Mr. Pereira gives an interesting account in his lectures*.

Tests.—But in these cases, as it is not difficult to attain the desired end, so neither is it to detect what has been done, by close inspection, or by reagents. The blackening depends on the formation of metallic sulphurets by the union of the lead, silver, or bismuth, with the sulphur either of the hair or of a solution of sulphuretted hydrogen applied for the purpose. Now, muriatic acid will extract the bismuth, and nitric acid the lead, from hair thus dyed; and by the proper tests, these metals may be readily detected in the resulting solutions. When nitrate of silver has been used, the process of detection will be a little different. Treat the hair with a solution of chlorine, by which chloride of silver is formed, which is soluble in ammonia, and again precipitable on the addition of nitric acid; in which state it may be readily detected by the usual means.

Means of making the hair of a lighter colour.—When the object is to render dark hair of a lighter colour, it is obtained by the employment of chlorine; first washing the hair with water of ammonia, in order to remove all greasiness. One part of strong liquid chlorine, diluted with four parts of water, will change, in the course of two hours, according to Orfila, black hair to dark chesnut. By successive im-

mersions in a solution of the same strength, it will be brought to a bright chesnut. If the same hair be brought to a deep blond colour, it may ultimately be rendered a bright yellow, or white, with a yellowish tinge. Another effect of these successive and prolonged immersions, is to render the hair very stiff and brittle.

M. Devergie, in his experiments on this subject, has found, that when the chlorine is strong, it does not destroy the colour very uniformly; there may be seen in the hair experimented upon a variety of tints; nor is the full effect of whitening produced in less than twelve, fifteen, or twenty hours. In regard to the effect of combing out the hair in solution of chlorine, MM. Devergie and Orfila are at variance. Orfila says, that by this treatment he has brought black hair to a deep brown in a short time, and that probably, if the process were continued for several hours, and the solution employed were stronger, the result would be the same as that from maceration. But Devergie has tried the method in repeated instances at the Morgue, and has never produced more than very slight, if any, effects.

As medical jurists, I fancy we shall not often have to deal with circumstances like those described. Whoever wishes to dye his hair for the purpose of confounding his identity, will have to encounter difficulties which will probably lead to his detection. The altered colour is not permanent, since, as the hair grows, the new hair, or the new portion, has its usual colour; while in all cases the proceeding is troublesome, and must occupy considerable time. The requisite chemical knowledge, besides, for performing the process adroitly, is not common; and the probability, after all, is, that it cannot be done by any hands, however expert, uniformly, and so as not to display various tints on a nearer inspection.

We shall now proceed to sum up the principal points to be attended to in investigating cases of doubtful identity.

Practical rules.—M. Orfila has suggested a good set of practical rules, which we may adopt with some slight modification: 1. The determination of the sex and age of the individual should be effected, though the latter be only possible to be ascertained in a rude way. 2. The stature should be determined. 3. The form of the head and its size ought to be noticed: the hair, whether it be thin or thickly grown; whether the forehead is prominent or retreating; the eyes, whether large or small, sunken or projecting; the form of the nose, whether short, flat, broad, long, aquiline, or pointed; whether the lips are large or small—with or without scars; the teeth, as to number and regularity of arrangement; whether the mouth is big or little; the chin single or double, with a dimple—

* MEDICAL GAZETTE, vol. xviii. p. 312.

pointed or round; the beard, whether thin or tufted; the size and shape of the countenance. 4. The neck, whether short and thick, or thin and remarkably long. 5. The chest, whether well or ill formed; the shape of the shoulders, with reference to the spinal column; whether there be traces of gibbosity, and in what way—whether anteriorly, posteriorly, or laterally; whether the individual have a flat sternum, or be what is called hen-breasted; whether the ensiform cartilage be remarkable for any deviation from the ordinary shape; the breadth between the two bases of the scapula. 6. The size or breadth of the pelvis. 7. The extremities: the feet and hands—whether bulky, clumsy, or otherwise; the fingers particularly, whether long or short, as compared with the hand or with one another; whether the knees are turned in, or bowed; the ankles projecting more than usual; the feet long or short, well proportioned, or broad and flat; whether there be any difference in the length of the legs, or any deformity. 8. Whether the genital organs, or other parts, have any peculiar malformation. 9. Congenital spots on the skin; for these are indelible, while warts or tumors of any kind may be removed by caustic. 10. Cicatrices from burns are good proofs of identity, or where they result from wounds or the spontaneous opening of tumors; for marks of this kind are never effaced, and may often, by reason of their situation, their form, their direction, or extent, furnish us with valuable indications. And, 11. Whether there be any traces of fractures or luxations.

These are all the marks and tokens of identity on which we as medical jurists can rely. As for a number of other points mentioned by authors—such as the beauty or ugliness of the individual, his leanness or plumpness, the colour of the eyes and hair—all these are capable of alterations in the course of time, and the latter, as we have seen, by art, which render them not to be depended on. The age of the person—the passions—the diseases to which he is subject—the climate in which he lives—the kind of life he leads—the nature of his diet, and a thousand other things, influence the body in respect to the transitory signs just mentioned. The well-known lines of Sir Walter Scott may perhaps be not inappropriately quoted:—

*Danger, long travel, want, or woe,
Soon change the form that best we know;
For deadly fear can time outgo,
And blanch at once the hair.
Hard toil can roughen form and face,
And want can quench the eye's bright grace;
Nor does old age a wrinkle trace
More deeply than despair.*

As for placing any reliance on mere resemblance, the testimony of ordinary observers, the recognition of parents, friends, and relations, or even very often on docu-

mentary evidence, which there are so many ways of forging, enough has been said to inculcate a proper degree of caution.

Ere I conclude I should wish to bring to your notice one case more, which, if not very instructive, may be at least amusing. About three years ago, a dead woman was taken out of the river at Blackfriars' bridge, and an inquest was held on her. She was identified as Eliza Baker, aged 17. A Mr. Wood first came forward and identified her: she had lived with him as a servant, but his wife growing jealous of her, she (Eliza Baker) was turned off. The master was evidently very much attached to the deceased, for he cut off a lock of her hair before the jury, and betrayed the utmost grief. He also fetched the deceased's parents: and they too, upon seeing the body, were loud in their lamentations. There were a number of witnesses examined, mostly relatives, and they all swore positively to the body. When Mr. Wood, the alleged seducer and destroyer of the girl's peace, was called upon to give his evidence, he was so overcome by his feelings at the melancholy occurrence, that nothing could be made of him; in fact, he was like a man in a state of stupefaction.

(I extract the remaining details from the *Times* report.)

"Mrs. Wood, the wife, was called in; she is twenty-eight years older than her husband, and shook her head at him, but nothing was elicited from her, her passion completely overcoming her reason.

A jurymen.—The more we dive into this affair the more mysterious it appears against Mr. Wood.

This remark was occasioned on account of some marks of violence on the body; there had been a blow on the nose, a black mark on the forehead, and a severe wound on the thigh.

The jury were commencing to deliberate on their verdict, when a drayman in the employ of Messrs. Whitbread and Co., brewers, walked into the jury-room, and said that he wished to speak to the coroner and jury.

Mr. Carter.—What is it you want?

Drayman.—I comes to say, gentlemen, that Mrs. Baker's daughter, you are now holding an inquest on, is now alive and in good health.

The coroner and jury (in astonishment).—What do you say?

Drayman.—I'll swear that I met her to-day in the streets, and spoke to her.

The coroner, witnesses, and jury, were all struck with amazement, and asked the drayman if he could bring Eliza Baker forward, which he undertook to do in a short time.

In the interim the jury and witnesses went again to view the body of the deceased. Mr. Wood shed tears over the

corpse, and was greatly affected, as were all her relations. The drayman's story was treated as nonsense, but the jury, although of the same opinion, were determined to await his return.

In about a quarter of an hour the drayman returned, and introduced the real Eliza Baker, a fine looking young woman, and in full health!

Several of the jurors remarked that they never saw such a strong likeness in their lives as there was between Eliza Baker and the deceased, which fully accounted for the mistake that the witnesses had made.

The whole scene was most extraordinary, and the countenances of witnesses and jurymen it is impossible to describe.

There was no evidence to prove who the deceased was; and the jury, after about eleven hours' investigation, returned a verdict of 'Found drowned.'"

ON DRACUNCULUS.

(CIRCULAR.)

Bombay, May 9, 1836.

*To the Medical Officers in Charge of
H. M.'s Regiments.*

SIR,

I BEG to transmit to you the following extract from a communication from the Director-General, upon the subject of the Inspection Report upon the Hospitals of this presidency:—

"You will, I hope, encourage by every means in your power the use of the stethoscope, an instrument the value of which is every day becoming more evident.

"The subject of Dracunculus is one, too, which is well worth the attention of the scientific inquirer; and I have to request a special report may be required from each medical officer under your superintendence, who may have had opportunities of investigating the subject. It may be sent with the next annual sick returns, but disjoined from them so as to admit of being bound up separately. It may facilitate the inquiry, if you will circulate a few queries to each medical officer, and transmit to me a copy of the same, as well as your own review of the answers."

With respect to this last subject of dracunculus, I beg to propose the queries which follow, as seeming to embrace the more important points of the

inquiry; but still with the wish (as my own opportunities have been but desultory and infrequent) that officers would, if they see fit, modify or add to them, so as to comprehend, in the way most consonant with their own opinions, the whole subject which is thus submitted for our investigation.

It may be convenient to assume, as a consequence from very general assent, that the dracunculus is an animal within the tissue of the human body, and that it produces a disordered state of the part, which (disorder), although it may resemble other irregular actions, has the specific appellation of its cause; and having assumed so far, it remains to determine, if possible, its own nature—its times of appearance—its characters as disease—and the rationale of cure.

1. What is the organization of the dracunculus; and, as corollaries, what its mode of movement, of nutrition, and of reproduction?

2. Has climate (in the widest sense of the term), and has season, influence over its appearance in the human body? Does sex, age, or temperament, dispose or indispose to its appearance in the subject?

3. What the symptoms which mark the existence of dracunculus in a part?

4. Rationale of cure?

I have the honour to be, sir,

Your most obedient servant,

(Signed) CHARLES COLLIER,
Deputy Inspector-General.

This circular was addressed, in the month of May last, to each medical officer in charge of corps; and the several acknowledgments of it are herewith submitted. By these it appears that nothing has been added to their former knowledge of dracunculus, either upon the nature of the animal, its immediate influence upon the human body, or the principles of cure. Indeed, the whole of our knowledge concerning dracunculus may be comprised in the following theorems:—That it is an animal; that it appears in the cellular tissue of the body, and most frequently, but not universally, in the lower extremities; that, sooner or later, apparently while making its way to the surface, it causes disturbance of the part; and that this, like other local disturbances, affects the constitution variously, according to age, temperament, and state of health at the

time. Although nothing beyond mere conjecture has yet been offered respecting its production, its habitat, and mode of admission into the body, all are agreed that its presence is confined neither to person, to sex, nor to age—facts which make still more mysterious its nature, and still more difficult the application of prophylactics.

It is almost trivial to note, that the dracunculus is the *Filaria medinensis*, both of Cuvier and Lamarck; that the former has ranged it in his first Order, "Nematoidea," of Entozoa. The latter is a section of his second order of Vermes; and that both hold it to be essentially a zoophyte. The organization of Dracunculus has not been made out, it would appear, by any member of our service, and only one opportunity of examining a recent specimen ever offered itself to me; but from that examination I could satisfy myself upon little beyond the broad facts that it was an animal; that its body was tubular, and composed of two tunics; that these were fibrous; that there were nervous cords, or traces of cords like such, and that the contents of the tube were fluid. This is the extent of my knowledge of its structure, and although very scanty, yet but little more is given by either of the eminent naturalists who have been alluded to. The characteristic features of the class laid down by M. Cuvier seem to involve a contradiction or else an anomaly; and it is scarcely possible, after an attentive perusal of the description, to avoid the inference, that the author himself was hardly satisfied upon the subject, and, therefore, that his language became obscure and contradictory.

The difficulty, says M. Latreille (who compiled this part of the work) of conceiving how they (the Filarie) attain the part where found, joined with the fact of their not having been observed out of the body, has given rise to the belief of spontaneous generation. It is now certain, not only that the greater part produce ova, or living prototypes, but many have sexual distinction, and copulate like ordinary animals (*animaux ordinaires*). We may, then, believe that they are propagated by germs, small enough to be transmitted through the narrowest ways, or that often the animals in which they live bring with them, at their birth, the germs; in other terms, that the Entozoa may be connate.

This general description of the class, alike vague and contradictory, is not made clearer by either of these able naturalists in their account of the genus of *Filaria*; so that even after their labours, all the more interesting facts pertaining to Dracunculus are yet desiderata in science. "There can be perceived," it is further said by M. Latreille, in his account of the 'Class,' "neither tracheæ nor other organs of respiration, and, therefore, that the influence of the oxygen can be communicated only by the medium of the animals in which they live: they have no trace of a circulation, and traces only of nerves, but those so obscure, as to have justified doubts upon their existence at all." The description of the Dracunculus itself is well given both by M. Latreille and M. Lamarck, and it answers to that which is the subject of this paper—a body, long and filiform, having at its extremity the round opening of the mouth, resembling closely the Gordii; and again, "*Corpus teres, filiforme, subæquale, lævigatum, sæpe longissimum, rigidiusculum. Os terminale, orbiculare, minimum.*"

The generic history of *Filaria*, by M. L., is not satisfactory, because it assumes what has never been proved, and also what would seem to be hardly compatible with the facts. After stating that it is very common in warm climates, it is said to insinuate itself (*s'insinue*) under the skin, especially of the legs, and there to develop itself to a length of ten feet and upwards; that it may remain there many years (*plusieurs années*) without exciting very evident sensations, but yet that sometimes it may produce, according to the part attacked, acute sufferings and violent convulsions: and when it does show itself, to be seen from without, then it is laid hold of, and drawn out very slowly from the dread of breaking it. Its size is that of a crow-quill. Its distinguishing feature is, the end of the tail being both hook-like and pointed.

It can scarcely be necessary to show the vagueness and the contradiction of much of this. After confessing the difficulty of conceiving how the Filarie gain admission into the parenchyma, and acknowledging their never having been met with apart from the body, yet they are said to insinuate themselves beneath the skin, without one fact having been adduced to prove the entrance, or

ment advanced to show its position. The Filarie, like Entozoa, be zoophytes; and of them all our age may be said to be negative, before obscure: we know neither origin, their mode of nutrition, where they attain the place where found.

observed by M. Lamarck, that, as, during which observations are going on, intestinal worms of several species have been met with where but in the bodies of animals, where, neither in the earth, the air, or in the interior of plants, are analogues to be met with."

As to its appearance in the human body, the same author says it inhabits subcutaneous cellular tissue, especially the legs and feet of men, and in the warm climates of Asia, Africa, and America. Is, he asks, the disease developed there where it is found, or introduced from without? This (of introduction) is yet doubtful, therefore its genus has been un-

Some individuals have been more than two feet in length; some species in other animal bodies (Simia genus), gracilis—of birds, and others,—"attenuata,"—"ovata,"—"brevi."

This branch of the subject has been discussed in great part already—has to do with the appearance of the worm, since it is found only in warm climates; but then as it is not found in all, (it is not found, for instance, at the Mauritius, which is like Bombay (excepting in substance there). Its topography tracked out is yet a desideratum; and as the number of cases of it have increased in the hottest months, season after season, it seems to have something to do with climate; and yet, as if to baffle

generalization, while common in some, not an instance of it has been observed in the contiguous cantonment of Calcutta. The observation of Dr.

which has been extensive, supports the inference that the male is more common to it than the female, and the same in the child; but relatively so. "all (he observes) are obnoxious to its invasion." Dracunculus is little known; in fact, over India under varying conditions of soil, water, and even temperature; whether it be found on ground so as to cause a lower mean average

temperature than the plains, there is no facts to show.

3. The pathognomonic signs of the presence of dracunculus in a part, is the appearance of a bleb (bulla), or large vesicle, with, as it may be supposed, inflammation, greater or less in extent and in intensity, according to circumstances: at the bursting of the vesicle, a small circular aperture is perceived, and soon the end of the worm is found, either projecting through, or else beneath it. As this is the commencement of the worm's passage outward in most instances, so a bulla becomes a proof, although not universally good, of the animal's existence beneath. Exceptions to this law are noted by M. Latreille, and, indeed, both by Dr. Perston and by Dr. Wilkins. Sometimes the worm may be felt beneath the skin, without the party having been conscious of its presence; sometimes, on the contrary, the part may be tumid and red, and painful, without any trace at the moment of the animal; and again, a sudden sense of pain, as from a thorn, and then, as Mr. Wilkins has observed, the dracuncle to be manifested. But the pathognomonic sign, subject, as it has been said, to some exception, is, a bleb, with slight surrounding inflammation, and at the rupture of the cuticle a small circular aperture: beneath which lies the worm; constitutional sympathy depends upon appreciable causes, of course, but this, when all conditions are estimated, may be affirmed to be strangely low. There is a tact in detecting dracunculus, which, like all experimental knowledge, may be gotten only by practice. Experience is required, that is, for the diagnosis, as it is, for the surer removal of the cause; but this leads me to the last of the considerations.

The rationale of cure consists in the removal of the worm whole, (for, if broken in the attempt, the fluid exuded from it excites higher inflammation) if possible; but if that may not be, by gradual extraction, day by day, taking care to retain the part already drawn, by a simple yet easy apparatus. This is the method followed by the native medical men as well; and, indeed, as it is not possible to follow, in many instances, the windings of the worm, and as further mischief results from it if ruptured, it seems to be the only one practicable; there is some

tact, of course, required for the practice, but, then, it is a tact which is easily gotten. Warm, or rather hot, fomentations are preferred, while the worm is yet in its nidus, and so they are, indeed, through all the subsequent processes. It has appeared to me, and the suggestion has been offered, that evaporation by cold lotions would act better; but my clinical opportunities have been too few to give terms for comparison. The method of extraction is, no doubt, tedious (the average period of cure being not less than a month), and it acts prejudicially, by the confinement and the suffering, upon the health; sometimes, also, especially when in the neighbourhood of a large joint, the local inflammation is so vehement and extensive as to be a source of sinuses and other and further mischief than had first been done. As such consequences, when they do happen, come within the general domain of surgery, they need not be dwelt upon here. The constitution is to be attended to, and the actions of the part quieted by position, by free openings for the discharge of fluids, and by suitable applications.

It has sometimes occurred to me, I confess, that it would be better, when dracunculus had made its appearance in a part, if the whole matter were taken into the hands of the surgeon; the worm extracted by incisions, if possible, and if not, extracted entire, believing that such would, by their own operation, be preferable to the process resorted to; but more opportunity, and the consideration of others' opinions, have altered, or modified at least, that impression.

To sum up, then, what is known at this presidency, upon dracunculus and its treatment, in order that our knowledge may be compared with, and elucidated by, inquiries at other places, the following generalization is submitted:—

I. Dracunculus is a round thread-like worm, attaining a length of *two feet and upwards; and it is found in the parenchyma of the human body, extensively over India, without much respect for age, or sex, or condition. Its appearance, though not confined to, is

most common in, the hot dry months; but then capriciously appearing, in many instances, at one place, and not at all at another in its neighbourhood. The worm consists of two tunics, which are evidently fibrous; it is furnished with an orbicular mouth at one end, at the other (which is pointed and curved) is the anus, and a tube or alimentary canal is extended, probably, between them. There are traces to be perceived of what appear like nervous cords, but here is closed our knowledge upon its structure. Nothing is known about its circulation, if any, its mode of nutrition, reproduction, or existence in the part where found; all these general facts belong, indeed, to that vast family of Being at its source, where objects, by their minuteness, and by, so to say, their peculiarities of existence, baffle observation and elude inquiry. Speculation may be hazarded, but speculation can form no base for therapeutics.

II. Climate has to do, no doubt, with dracunculus, since it does not exist, so far as it has been hitherto learnt, excepting in warm latitudes, but then not continuously; preferring, whatever the cause may be, one spot to another, and the hottest dryest months are those most suited for its development; but, under suitable circumstances, there is no exemption to be found in age, or sex, or condition of life.

III. The symptoms are a bleb, or else a large vesicle, with slight surrounding inflammation, and, at the bursting of the cuticle, a circular aperture to the worm beneath; occasionally erythematous appearance, without bleb or vesicle; sometimes the worm itself to be felt under the cuticle, without local action or disturbance of any kind.

IV. The removal of the worm whole, if possible, at once; if not possible, whether from local attachment or from depth of situation, then by the process of extraction, which is well described by the officers who have seen much of the affection.

This method, or process, is soon acquired, as it is easily practised (indeed the patient mostly ministers to himself), and it involves very little pain. The objections to it are its tediousness, and the injury which may be sustained by the health during the period of cure. Now it was to avoid both these results that a bolder surgery offered itself to me as preferable; assuming that, at the

* This, which is the length of the animal, as given by M. Lamarck, is confirmed by the experience of medical officers here. Dr. Perston has never seen one which exceeded three feet, but Latrelle affirms, upon others' authority, that it does sometimes exceed even ten feet.

worst, failing to remove the worm at once, it would still place parts in a better state for supporting the secondary actions, and to expedite recovery. But this impression has been much modified, both by my own and by others' experience, and I am now content to witness the slow process of extraction, as being, on the whole, the safer mode of cure. The matter is altogether peculiar, and so must be, apparently, the management of it.

CHARLES COLLIER.
Dep. Insp. Gen. Hosp.

CASE OF COMPOUND
DISLOCATION OF THE ASTRAGALUS
AND OS NAVICULARE.

To the Editor of the Medical Gazette.

SIR,

I BEG to inclose you a very rare case of compound dislocation of the astragalus and os naviculare, if you have room to place it in your valuable journal.—I am, sir,

Your obedient servant,
C. M. BURNETT.

Alton, Hants,
July 10, 1836^a.

Colonel G—— is an active man, of a spare habit of body, upwards of 60 years of age. On the 23d of February last he was fox-hunting, and had made a leap, when suddenly he found himself unable to follow, in consequence of his right foot being displaced. His usual habit was to ride in his stirrup, the foot resting on its outer side. When I first saw him the boot had been removed, which, from the force of the injury, had given way, the bones protruding through it. The foot was dislocated inwards, at right angles with the leg; and two bones were plainly to be seen projecting out of a wound, which was about three inches in length, extending across the outer ankle.

I carefully examined the situation and shape of these bones: the upper one, the os naviculare, had projected its cuneiform surface outwards and forwards, in an oblique direction; and the other bone was the astragalus, which had forsaken its natural cavity, was

driven forwards and outwards, and presenting that surface which in its natural position would be in contact with the os calcis. I steadily kept pressure as firmly as I could, for nearly a quarter of an hour, upon the prominent os naviculare, in the direction of the joint, to which I was directed by the ends of the tibia, which was plainly to be seen beneath the astragalus. At the expiration of this time I had the satisfaction to see the bones slip into their proper places, and the foot resume its natural character. The end of the fibula was not fractured. Having placed the limb in proper splints, I conducted him home, where he was met by his family surgeon, Mr. Wickham, of Winchester, in whose able hands I had every satisfaction in knowing it would be watched with an active and intelligent eye. The case has done remarkably well; and by a letter which I have received from Mr. Wickham, he tells me—"I am able now to inform you that Colonel G——'s case has been brought to the most satisfactory termination. The wound is healed, the motion of the joint is perfect, and the swelling of the part is nearly reduced. Weakness, which time only can remove, and the occasional puffiness from use, are the only remaining effects of the injury. You are aware that the progress of the case has scarcely been interrupted, and that inflammatory symptoms only once occurred during the period of his confinement; these were ushered in by a rigor and succeeding heat; they occurred about three weeks after the accident, and only lasted a few hours. At present he is able to walk with crutches, without the least inconvenience, and the limb bears occasionally its share of the weight of the body. As to the motion of the joint, it cannot only be performed by myself, but he can freely bend and extend the foot."

Upon this very interesting case allow me to make a few observations.

As I have not been able to hear or read of a similar case to this, it may be doubted whether the os naviculare was really displaced; but of the existence of the fact I cannot be deceived, for I saw and felt both this bone and the astragalus before they were reduced. And as I was enabled, by keeping up a long-continued pressure in the most favourable direction, to reduce the joint

^a The paper only reached us last week.—ED. GAZ.

to its natural state, it is reasonable to infer, in all cases where the astragalus alone has been dislocated, that it may by perseverance be replaced; although we admit, where dislocation of the foot has not taken place, this operation is rendered more difficult. The consequences of this bone not being replaced involve its death and subsequent extraction, if amputation be not resorted to previously, to shorten the process of mortification which would otherwise take place. Delpech mentions three ways in which the astragalus can be dislocated*, one of which, where "the bone is completely thrust out of its natural position, and thrown upon the dorsal surface of the tarsus," is the nearest approach to the present case; for here it would have taken its place on the dorsal surface, accompanied by the os naviculare, had not the tarsus been dislocated inwards. He says, "in a case of lateral luxation of the foot, we have seen the astragalus completely thrown out of its natural position, and carried on the dorsal surface of the cuboid bone; and what is still more singular, notwithstanding the great displacement, which supposes a complete isolation of the bone, on making use of the necessary extensions on the leg and foot, while making at the same time compressions upon the astragalus, in a direction from before backwards, it was brought back into its natural situation, the luxation of the foot was reduced, and an easy and rapid cure was obtained; and the bone thus displaced preserved from necrosis†." It seems, if the astragalus is to be preserved, and the joint completely restored, it must be reduced. In those cases recorded, where this bone has not been reduced‡, necrosis has taken place, followed by its discharge or extraction; and though the foot has been spared, it has been at the expense of shortening, and almost ankylosis.

There is every probability, if the dislocation in the present case had not been reduced, that the displacement of the two bones would have occasioned the loss of the entire foot.

TWO CASES OF PERICARDITIS; WITH AUSCULTATORY DIAGNOSIS AND REMARKS.

To the Editor of the Medical Gazette.

SIR,

ABOUT twelve months since I read before the Physical Society of Guy's Hospital "Some Observations on the Diagnosis of Pericarditis," which, considerably contracted, were afterwards published in the first number of the "Guy's Hospital Reports." In that paper I made no mention of Dr. Watson as one of the contributors to the pathology of this disease. I think it, therefore, due both to that gentleman and myself, to state, that the cause of this omission was my ignorance of the fact of his having written upon the complaint, and that, till 22d instant, when looking over the sixteenth volume of the *MEDICAL GAZETTE* for another purpose, I had never enjoyed the advantage of reading his clinical lectures upon the subject. This, sir, to myself is a misfortune, as, agreeing with Dr. Watson in many important particulars, in some of which we both differ from some recent writers upon pericarditis; and having both arrived at our conclusions after strict observation of the disease, and without any communication on the subject, I should have been highly gratified to have been enabled to advance so distinguished a name as that of Dr. Watson, as a supporter of the opinions I then advocated.

In some minor particulars I differ from that gentleman, as will be seen by the observations appended to the two cases I herewith send, should you consider them suitable for the pages of your journal. The former occurred many months since, and I regret that but few notes were taken; it is therefore brief and general: the latter has taken place very recently, and is therefore more copiously and particularly detailed.—I am, sir,

Your obedient servant,

H. M. HUGHES, M.D.

13, Wellington-street, Southwark,
Oct. 29, 1836.

CASE I.—H. W., aged 18, a thin delicate youth, of pale face and light complexion, after exposure to wet and cold, became affected with rheumatism of a

subacute character, for which he came under medical treatment on the 15th of April. He was bled, and took the common medicines for rheumatism with very great relief. On the 18th, it was discovered that he had pain, and some tenderness on pressure, at the scrobiculus cordis, and at the intercostal spaces over the præcordial region. He constantly maintained the recumbent position without inconvenience, and turned to either side without much distress; though his pain was slightly increased by lying on the left, and his easiest posture was with the body partially turned towards the right side. He had no cough; his respiration was but very slightly hurried; his tongue was white and moist; and his pulse rather frequent, thrilling, and regular. The chest was resonant on percussion, and there was no unusual dulness in the præcordial region; the respiratory murmur was natural. The impulse of the heart was sharp, but not heaving; and its rhythm, as far as it could be ascertained, appeared normal. The first sound was replaced, or masked, by a *bruit de soufflet*, which was heard over the whole heart, but most clearly in the situation of the aortic valves; the second sound was scarcely audible. On the outer side of the left nipple was distinctly heard a double rubbing sound, the *frottement* of the French authors and Dr. Stokes, the "*to-and-fro* sound" of Dr. Watson. It had no similitude to the *creaking* of new leather, but exactly resembled the noise produced by the friction of two rough and rather soft surfaces. It was confined to a small circumscribed space, was very superficial, and perfectly distinct from the *bruit de soufflet*; which, moreover, appeared to be produced only during the systole, whereas the *frottement* evidently accompanied both the systole and diastole of the ventricles.

He was ordered to be cupped over the region of the heart, and to take Calomel, gr. j.; James's Powder, gr. iv.; Ext. of Henbane, gr. iij. every four hours, in a simple saline draught.

On the 20th the gums were slightly affected; the pain was rather less; the rubbing sound less distinct, and heard over a still smaller space; but the bellows sound remained as before.

The pills, &c. to be continued three times a day only.

On the 23d the *frottement* had nearly, or quite disappeared. The *soufflet* was still distinct; and some pain and tenderness remaining, fifteen leeches were applied with temporary relief.

On the 27th, some pain still existing, twenty more leeches were applied. The *frottement* had entirely ceased, but the *bruit de soufflet* was yet very distinct; the respiration remained but very little affected.

He was now ordered Antim. Tart. gr. $\frac{1}{2}$, Opium, gr. $\frac{1}{2}$, and Calomel, gr. ij. every night; and a mixture with Tr. Digitalis, $\mathfrak{m}\mathfrak{x}$.; Nitr. Potass. gr. xv.; and Sp. Æther. Nitr. $\mathfrak{m}\mathfrak{xv}$. three times a day.

About ten days after this he had some slight return of pain, for which, on May 7th, a blister was applied with benefit. On the 11th he was ordered decoct. cinchon. and sulphuric acid, and in a week or two returned to his employment, previously to which I ascertained that though the impulse of the heart was rather feeble, its rhythm and sounds were natural, and that no *bruit de soufflet*, even after walking briskly for a short distance, could now be discovered.

CASE II.—Samuel Barney, aged 31, a thin delicate-looking man, of light complexion and lymphatic temperament, became a patient of the Surrey Dispensary, under my care, 27th Sept. last. He is by occupation a dancing and music master, and has been very regular in his habits. He has been married six years, but has had no children. He has on two occasions previously been the subject of rheumatism; and though he does not recollect to have been affected at such times with dyspnoea, palpitation, or any symptoms of thoracic obstruction, he has been very liable to catarrh, and has more than once been confined in consequence of pain of the left side; and for the last year, when exerting himself more laboriously than ordinarily, has been troubled with dyspnoea, pleurodynia, and palpitation.

Two weeks previously to my seeing him, after exposure to cold and wet, he was attacked with rheumatic pains of the limbs, the increase of which had, for the last six or seven days, confined him to bed. I found him at my first visit labouring under subacute rheumatism. The wrists and ankles were swollen, rather red, painful, and very tender; the

tongue was clean and moist, with the exception of two broad lateral furred lines; the margins of the gums were ulcerated; the countenance appeared natural; the pulse 116, small, fluid, and regular; the respirations 22, and unembarrassed. He had no cough, nor any thoracic uneasiness, when perfectly quiet, but on deep inspiration felt some pain under the left breast, which I ascertained had first appeared on the previous day; he lay flat in his bed, and felt no inconvenience (except from pain of the extremities in the act of moving) by turning to the right side, though some uneasiness was produced by inclining to the left. There was some tenderness on pressure below the ensiform cartilage, but *none* at the intercostal spaces over the heart. The chest was generally fairly resonant on percussion, but considerable dulness and some contraction existed over the lower ribs on the left side, near the heart; the remainder of the præcordial region was not more dull than natural. The impulse of the heart was weak; the rhythm could not be ascertained, as, excepting over the ensiform cartilage, where it was indistinctly audible, the double flap of the healthy heart was replaced by an extensively diffused superficial rubbing noise, most distinct about one inch on the inner side of the left nipple, but more harsh and grating on the outer side of the same point; the former resembling the friction of two pieces of cloth, the latter that of rough horny surfaces. This sound did not accompany merely the first or second sound of the organ, but obscured both, and, though varying in intensity, appeared to be without intermission. The respiratory murmur was audible over the chest, excepting at the base of the left lung.

Ordered Hirudines, x. parti dolent.
Antim. Tart. gr. $\frac{1}{2}$. Opium, gr. $\frac{1}{4}$. Hyd.
Submur. gr. j. 4tis. horis; et Magnes.
Sulph. 3ss. Vin. Colch. 3ss. Mist.
Camph. 3iiss. ter die.

The next day I found the symptoms little changed; the pain as before; the bowels only once relieved, and then not from medicine.

V. S. 3x. vel prim. sign. deliquii. Rep.
Pil. cont. Mist. ad plm. alv. solutionem.

29th.—The bowels had been freely acted upon by medicine, the wrists and ankles were quite free from pain and

tenderness; he had passed a restless night. The dulness of the chest, sounds of the heart, tenderness at the scrobiculus cordis, and pain on deep respiration, remained as before. Respiration easy; tongue clean and moist; pulse 120, small, soft, and irregular, excepting that about every 60th beat, a little delay, not amounting to an intermission, was observable.

C. C. part. dolent. ad. 3x. Rep. Pil. c.
Hydr. Submur. gr. ij. Omitt. Mist.

On the 30th he could turn to either side without inconvenience, having found much more decided relief from the cupping than from the venesection; pulse 104, soft and fluid; skin natural; no mercurial action was evident on the gums; tongue slightly furred; impulse of heat, and dulness as formerly; no bruit is now heard at the scrobiculus cordis, but the natural sounds appear weak; below the left nipple was heard a harsh bruit de soufflet, or râpe, synchronous with, and following the systole of, the ventricles, and concealing the sound attending the diastole; above, and to the outer side of the left nipple, in addition to, and perfectly distant from, but still partially concealing this bruit, was a superficial rough rubbing, or grating noise, which was almost continuous, or at least had no regular and perfect intermissions.

Rep. Pil. 6tis horis, et Capiat Mist. si opus erit.

Oct. 1st.—Bruit softer, but more distinctly heard over a large space; pulse 96.

Rep. Pil. ter die Empl. Cantharid. regioni cordis; Capt. Haust. Efferv. 6tis horis.

3d.—The blister removed all remains of pain, but he now complained of some tenderness in the vicinity of the cæcum; no action of mercury upon the gums; sounds of the heart unaltered.

Pergat.

4th.—Fomentations had removed the abdominal tenderness; below the nipple was still heard a harsh bruit de soufflet, and above this point, and at its exterior the frottement still existed, but now consisted of three regularly successive sounds which may be thus represented—*tee te te—tee te te—tee te te*; tongue rather morbidly clean and smooth, not red; pulse 88, with the slight delay be-

fore observed occurring less frequently ; there was still no mercurial action, as evinced by the salivary glands or gums.

Pergat.

5th.—The rubbing noise had entirely disappeared, but both above and below the nipple was now distinctly heard the bruit-de-soufflet synchronous with the systole, and running into and obscuring the second sound of the heart ; pulse 96, slightly thrilling.

6th.—Alvine evacuations green from mercury for the first time, but still no appearance of salivation ; complains of some pain and tenderness in the right hypochondrium on turning or lying on the left side.

Pil. Hydrarg. gr. iv. ; Opii, gr. $\frac{1}{2}$ ter die.
Omitt. Mist. Appl. Hirudines vj. et
Fotus, parti dolent.

8th.—I this day heard for the first time that he was not only troubled with piles, but had passed some blood after each evacuation for the last two or three days ; bruit less harsh ; he now again complained of some pain and slight swelling of the wrists.

Decoct. Cinchonæ 3ix. ; Mucilag. Acaciæ,
3ij. ; Syr. Papaver. 3j. ter die. Pulv.
Ipecac. c. Opio. gr. x. om. nocte.

15th.—Pains removed entirely from wrists, but complains of some wandering uneasiness about the shoulders ; bowels relaxed, and evacuations still followed by a little blood occasionally. Bruit-de-soufflet much softer, and the second sound of the heart was now indistinctly heard over the cartilages of the third and fourth ribs.

Inf. Cuspariæ, 3iss. Pulv. Cretæ c. ʒj.
Liq. Opii Sed. miiij. ter die. Rep.
Pulv.

17th.—Bowels regular, and little or no trace of blood existed in the excretions. He slept well ; pulse 96, soft, and feeble. He had no pain ; respiration was easy ; the dulness of the left side had of late much decreased ; and over the portion of lung which afforded no indication of the ingress of air, was now heard a muco-crepitating rattle, which either did not formerly exist, or was concealed by the abnormal sounds of the heart. A soft bruit-de-soufflet was now observable over the greater portion of the præcordial region, but below the left nipple it was still harsh and loud, approaching to the bruit-de-râpe ; and at the base of the sternum

the natural double-flapping sounds of the heart were distinguished, still feeble, but pure. Over the cartilages of the third and fourth ribs it is now clearly audible, the second sound in its natural state.—Pergat.

19th.—Some uneasiness in shoulders ; tongue and bowels in a healthy condition. Ordered again—

Decoct. Cinchon. c. Conf. Aromat. ʒj.
ter die. Rep. Pulv. gr. v. om. nocte.

24th.—He continued free from pain ; the shoulders were now quite easy ; his appetite was good ; his sleep natural ; the dulness of the chest had almost disappeared ; the pulse was 96, and feeble ; and the sounds of the heart remained as at last report : believing them to arise from chronic affection of the valves, and probably to be beyond the reach of medicine, after giving many directions as to exercise, food, and clothing, I ceased regularly to visit him.

REMARKS.—There are few, I imagine, who, after an attentive perusal of the preceding cases, will have any doubt as to the presence of pericarditis ; though fortunately we had no opportunity of *absolutely proving* its existence. Yet none of the many distressing symptoms usually stated as characteristic of this disease, were here observable. The sense of burning and weight at the heart, and flushing of the left cheek, mentioned by Corvisart—the evident disparity between the forcible but irregular impulse of the heart and the pulse at the wrist, spoken of by Laennec—the increased dulness and projection of the præcordial region, considered of so much importance by Louis—were all absent ; for the dulness observed in the second case was clearly referrible to the lung or pleura, and was probably the result of some former attack. There was here none of the anxiety and violent oppression ; no dyspnœa, orthopnœa, or lividity of countenance ; no inability of motion from impending suffocation ; no disposition to fainting, or actual syncope ; no tumultuous action of the heart, or extreme feebleness, irregularity, or inequality of the pulse, often (and sometimes, indeed, truly) noted among the symptoms of pericarditis. But I am disposed to believe, that did the physician wait for the appearance of such indications previously to suspecting the presence of pericarditis, or

acting on his suspicions by the adoption of a vigorous antiphlogistic treatment, his patient would, in a majority of cases, be beyond the reach of remedies, when, at length, tardily applied. The conclusions of Laennec upon this disease, appear amply confirmed by cases such as the above, and those less frequent but more distressing examples referred to. "Ces faits," says he, "et plusieurs autres me paraissent prouver que, dans quelques cas, la péricardite même aigue est une affection locale très-peu grave, et dont l'influence, non seulement sur le système général, mais même sur celui de la circulation, est presque nulle; tandis que, dans d'autres cas, la même affection, au même degré ou à un degré inférieur est accompagnée de fièvre aigue, et d'un trouble de presque toutes les fonctions, assez grave pour compromettre la vie du malade." This striking difference of symptoms and of termination, I am induced, from observation and reflection, to believe depends (as I have already stated in the essay mentioned above) upon the different character of the inflammatory effusion, which in the one case is for the most part solid and in comparatively small quantity, and in the other fluid and abundant. Experience clearly shows that rheumatic pericarditis is, and must be, generally of the former character, as daily observation proves that it has been and is continually overlooked; which would be impossible if attended with the grave symptoms which accompany serous or sero-purulent effusion into the pericardium. The existence of such affection has, indeed, often been not even suspected either by the medical attendant or the patient, till the heart being irrecoverably and permanently deranged, and the symptoms of chronic disease of the organ being too decided to be mistaken, the observant practitioner inquires the previous history of the sufferer, and finds that formerly (perhaps some years since) he has been affected with rheumatism; since which he has been more or less troubled with pain of the side or shoulder, dyspnœa, and palpitation; and to which, therefore, the disease is clearly to be referred. I am fully convinced that a great majority of the chronic diseases of the heart are originally produced by a rheumatic affection of the organ, or at least an inflammatory attack of the pericardium, while

rheumatism is at the same time present in other parts of the body: and as thoroughly convinced am I, that few, very few, children and youths affected with rheumatism, escape this or some other inflammatory affection of the heart. Any one who chooses to inquire into the history and origin of the cases of heart disease presented to his notice, or to examine, by auscultation, the præcordial region of children suffering from rheumatism, submitted to his care, may speedily convince himself of the truth of these observations. Yet it is a lamentable fact that many practitioners, even of the present day, remain either ignorant or regardless of the *frequency* of such attacks, and that numbers of lives are perhaps, if not lost, at least considerably shortened by want of attention to their slightly obtrusive symptoms. I may here observe, that neither of these patients complained either of pain or tenderness, till after inquiry was made and pressure was used. Even then, they were so comparatively trifling that they might be not unnaturally attributed to rheumatism of the intercostals, or acidity of the stomach. Suspicions, however, of pericardiac mischief were excited by the nature of the cases, and the application of the stethoscope immediately changed suspicion into certainty; a characteristic rubbing noise was distinctly heard, which dispelled any remaining doubt, and at once clearly established the true nature of the disease, and proved the inestimable value of auscultation.

I have already stated it as my opinion, in opposition to that expressed by Dr. Stokes, that the *bruit-de-soufflet*, and *frottement* or *to-and-fro* sound, arise from different causes, and are produced in different parts of the heart. The circumstances observed in the cases, and particularly the second, related above, some of which were observed by other stethoscopists, as well as myself, are strongly confirmatory of this opinion. Thus in the progress of the case, the soufflet appeared deep-seated, the frottement comparatively superficial; the former was generally diffused over the heart, the latter confined to a small space; the former was evidently synchronous with the contraction of the ventricles, and regularly intermitted; the latter accompanied both contraction and dilatation, and though variable,

was continued; the one became more distant as the other gradually decreased; the one still remains, the other has entirely ceased. Dr. Watson, in his valuable clinical lectures on this subject, has stated his belief that the bruit de soufflet in these cases is dependent upon the inflammatory thickening of, or deposit upon, the valvular apparatus; that this bruit is seldom absent, and is often one of the first indications of mischief about the heart, and that it probably sometimes exists in rheumatic affections, without inflammation of the pericardium. With these opinions, my observation leads me perfectly to coincide; and in one particular alone do I differ from that gentleman. He appears to suppose that it is the *smooth* surface of the membrane covering the valves which is usually affected, and that the inflammatory deposit *upon* them, by diminishing the apertures through which the blood passes, is the cause of the sound; and he brings forward the granulation, or excrescences, occasionally met with upon the valves after death, as a proof of the correctness of his opinion.

Now (in England at least) it fortunately happens, I believe, that rheumatic pericarditis is rarely immediately fatal, however frequently it may shorten the period of life; and we, therefore, seldom have an opportunity of proving the coexistence of endocarditis in the first attack of the disease. We must therefore refer, for confirmation or refutation of this opinion, to the more chronic affections of the heart: we cannot have demonstrative proof, and must therefore, in a great measure, depend upon circumstantial evidence and analogy. These induce me to suppose that it is the tissue beneath the lining membrane, or the *attached* surface of that membrane itself, which is *usually* the seat of inflammation and effusion. This tissue is most constantly affected in diseases of the general vascular system; depositions in the coats of arteries almost always occur behind, and not upon the internal lining membrane; atheromatous, cartilaginous, and ossific deposits, are exceedingly common *beneath* the membrane covering the valves, the unattached surface of that membrane remaining smooth and polished, and are very frequent in chronic diseases of the heart, a very large number of which appear distinctly referrible to rheuma-

tism, whereas the granulations or excrescences are, according to my experience, comparatively rare.

Seeing, then, that the bruit de soufflet usually appears early in the disease, continues throughout its progress, and often remains during life, at least upon slight exertion; that this bruit is now, I imagine, generally acknowledged to be dependent upon disease of the valves in chronic affections of the organ; that in these the deposit is beneath the membrane, and that they are frequently, perhaps generally, the result of inflammation accompanying rheumatism, it does appear to me natural to conclude, that the original inflammatory effusion or thickening occurs below, or on the attached surface of the membrane. It is true that the granulations, or excrescences, as they are *called* (I say called, for I believe they are not a *morbid growth*), may possibly become absorbed, and disease going on, and the bruit remaining unaltered, other matter may at the same time be deposited in a different portion of the affected valves: this is possible, but it appears not probable.

On the treatment of the former case I make no observations, as it was not under my own direction. On that of the second I have to state, that mercury, which I regard as our sheet-anchor in these cases, was given quite to the extent that I thought justifiable, particularly as, though the ordinary constitutional effects were not produced, after it had been regularly administered for many days, all the symptoms gradually decreased, and finally altogether disappeared, with the single exception of the bruit de soufflet, which I have every reason to believe was the result of some former attack. I was led to adopt this opinion not only by the previous history of the man, by his having before suffered from rheumatism, and, though he supposes on different occasions, from pain of the side, and from dyspnoea, and palpitation upon exertion, but by the decided dulness and slight contraction of the part said to have been before affected. It is, however, interesting to notice the decrease both of the harshness of the bruit, and of the dulness on percussion, over the diseased portion of lung into which the air now evidently passes, though with considerable difficulty.

The heart disease appeared so en-

tirely a local affection, that I did not, on the first day, think it necessary to abstract blood generally, especially as it has been observed by some, and I think also by myself, that topical often affords more decided relief than general bleeding. The lancet was, however, used on the second day, but simply as a precautionary measure; and the expressions of the patient certainly indicated that the benefit obtained by cupping was considerably greater than that afforded by the previous venesection. The above remarks on the relative advantage of local bleeding are, of course, intended to apply solely to the disease under consideration.

OPIUM IN INCIPIENT INFLAMMATION.

To the Editor of the Medical Gazette.

SIR,

I FEAR the crowded state of your journal can hardly afford space for the accompanying observations on opium; but should you find room for them, it may fix general attention on a subject which we have all too much neglected.

Your obedient servant,

RICHARD BURKE, M.D.

3, Sackville Street,
Nov. 7, 1836.

For some time back my attention has been directed to the employment of opium and its preparations, as preventive remedies, in the early stages of irritation, with a hope of checking inflammation; but the few opportunities which private practice affords, of working out any theory, however simple, induce me to call the notice of the profession to it, through the medium of the GAZETTE. If I could succeed in fixing upon it the attention of our hospitals, where alone medicine can hope to make any advances to the nature of a fixed science, I shall, in some degree, have attained my object. The question is of paramount importance, and cannot rest where it is.

In the range of the materia medica, there is not a drug which has been so extensively used, under every form, and in almost every disease; one to which

the system so readily accommodates itself; and yet scarcely one upon which there are so many contradictory opinions.

As the views which I here propose have reference to the employment of opium in irritation, so as to check the second stage, which is inflammation, it is of the last importance to have correct ideas of irritation. It has been variously defined by men of eminence, but differing little in substance. It is the exaltation of the organic action of a part, which is attended by inflammation when the irritation extends to the capillaries, and has been considered the primitive and principal form of the greatest number of diseases. In some it enters only as a secondary form, whilst there is another class, characterized by a sinking of all the powers of the system, into which it is supposed never to enter. The three elements which enter into the composition of irritation are, an exaltation of sensibility; an afflux of fluids to the capillaries of the part; a sojourn of those fluids there. In considering this question, our attention cannot be too closely directed to the following facts:—That without previous irritation there can be no inflammation, nor irritation without excitation, nor this last where sensibility does not exist. Irritation, when unaccompanied by inflammation, cannot be fairly called a morbid phenomenon. Broussais defines irritation “that state of an organ where excitation is carried to such a degree of intensity, that the equilibrium resulting from a balance of all the functions is broken.” John Hunter says it is “a disposition to act without the power to act.” But all these leave us still as much as ever in the dark as to the essence of irritation.

We can have but a confused idea of the influence which irritation exercises over the production of disease, without an accurate knowledge of the nervous system, to which at first it is limited, but which, when inflammation appears, extends to the vascular system.

The loose way in which medical men, until very lately, viewed the question of irritation, has most certainly led to serious errors. The simple, but comprehensive axiom, of *ubi stimulus, ibi fluxus*, was quoted only to be forgotten; and yet there are few to which we should more carefully attend. The first material character of inflammation is an

afflux of fluids to the interstices of the irritable fibre, but until this deposit take place disease is hardly imagined. It would, then, appear, that if this deposit were prevented, disease could not occur. It is generally laid down in books, that narcotics have the property of allaying irritation, if applied at a very early period, and that thus inflammation is checked.

For the theory of combating irritation, in its early stages, by exhibiting narcotics, we have the authority of Sir Everard Home, in the view which he takes of the influence of the nerves upon the action of the arteries, where he thinks inflammation depends upon the afflux of blood caused by the irritation of the nerves, and then concludes, that allaying the nerves is the best antiphlogistic.

There are two points which demand our serious consideration before we prescribe narcotics; if possible, to ascertain whether it be the ganglionic or cerebral system that is engaged. This is a point I fear not much attended to. If positive and manifest inflammation do not exist, then only do the majority of us prescribe narcotics. It is needless to say that this is not the only stage in which they may with safety be applied. In that restless agitation which sometimes succeeds fever, there is nothing to be compared with opium. Frank, no mean authority, tells us, "that when an intense pain, an excess of sensibility, a vivid affection of the mind, threatens an inflammation, a large dose of opium immediately after bleeding very often wards off the disease". Bleeding alone will not do, for we know that though we leave but one drop of blood in the body, that drop will, despite our bleedings, obey the summons of the irritating cause*.

At a meeting of the Royal Medical and Chirurgical Society, Dr. Yelloly, last year, made some very curious and interesting observations which bear directly on this subject. He does not think that vascular appearance from disease always necessarily denotes the existence of inflammation, and supported his views by producing a portion of the spinal marrow, which was highly vascular, but which was dependent, not

on inflammation, but venous turgescence. From this we see that the mere fact of increased redness should not necessarily direct us to the lancet.

Upon the precise operation of opium we have much to learn: whether it act directly, by diminishing the secretions, or by rendering the membranes upon which the fluids are poured out, as in diarrhoea, insensible to their stimulating qualities, is still a question. One thing clear is, that it is with one or the other intent it is generally exhibited. If we find it useful in the case of inflamed membranes, where by checking the secretion it stops the first process of inflammation, it is not going too far to extend the same reasoning to muscular inflammation in its incipient state. Is it too much to say, that opium may act in another way than on the attributes of the solids—excitability, sensibility, contractility? Sir Gilbert Blane hints that it may act on fluids, from the property of life which the blood is supposed to possess, and illustrates his view by the well-known fact, that the healing process of many ulcers is retarded by the existence of morbid irritability and sensibility, and which being allayed by opium, the cure is completed by nature.

We look in vain to the works of the earlier writers on medicine for information on this head; the limited knowledge which they had of anatomy, and which led them to confound, under one common denomination, nerves, ligaments, aponeuroses, and blood-vessels, is at least some excuse. Until we come down to Sydenham, there is little of interest on this subject. That great man viewed it under three heads, to which he reduced the pathological phenomena which yield to its influence—severe pain, vomiting, and copious dejections. To allay pain is of itself of paramount importance, for it alone will often destroy life. The late Dr. Pemberton spoke from sad experience, when he said that pain was the greatest sedative in nature.

Looking at the various diseases in which opium is given, in one form or another, we must admit that there is something in the operation of this drug which we are as yet not thoroughly acquainted with. The ordinary diseases in which we see it given are inflammations, or injuries of such a nature, either

* Andral's Pathology.

from accident or design—as amputations, or sprain, which induce inflammation so rapidly as to leave no time for its exhibition as a preventive remedy. In such cases its exhibition is based upon empiricism, solely with a view to procure a temporary respite from pain. I am strongly disposed to believe that opium does a great deal more even in those cases; and if we could but shake off our little prejudices, which cramp our better judgment, opium, instead of being given as a placebo, which is unfortunately too often the case, would become a leading feature in the subjugation of positive disease.

Our attention has not been sufficiently directed to the consideration of abstract pain; it is, unhappily, too often viewed as a symptom, when it is really the disease itself. I am led to this conclusion by the operation of corrosive poisons, which, when taken into the stomach, often destroy life by their action on the nervous system, and which is marked by extreme pain, when, after death, we are unable often to discover any change of structure in any organ or tissue. May not the custom of the Arabian physicians, and which has its followers even amongst ourselves, of giving opium largely and successfully in intermittent, be accounted for in this way—that by rendering the system insensible to the stimulus of disease, it thus cures it? or is it that the nervous system, which opium is supposed by some to select for its operation, is the seat of intermittent fever? In this there is some probability, for we find it given by men of reputation, both in the hot and cold fit.

I have experienced in my own person the good effects of opium, if taken in the incipient stage, when catarrh threatened. Half an ounce of laudanum, in an ounce and a half of liquor ammoniæ acetatis, taken at bed-time, has frequently allayed incipient catarrhs; but danger is to be apprehended if we allow the first ten hours to elapse before we apply it, for the catarrh is then inflammation, which is sure to be aggravated by it. The part which opium plays in that very distressing disease, colica pictonum, is, I am inclined to think, to be ascribed to the power which it exercises in subduing irritation. A patient suffering from this complaint, took, in three days, 96 grains of opium and 6 oz. of the syrup

of poppies, without feeling the slightest disagreeable sensation. At the expiration of three days, all pain ceased, and the bowels were easily moved by mild aperients. A very curious and ingenious theory has been offered, I forget by whom, to account for the part which opium plays in some thoracic diseases. It is supposed, that by shortening the respirations, less blood is admitted into the lungs, and consequently a diminished quantity of stimulating fluid reaches them: that under its employment the blood becomes less vivifying, no longer excites the arteries and tissues, whose life it was intended to maintain. This is not altogether visionary. Opium, we know, has some direct effect on the blood, though we are not yet prepared to say what that is. In cases of poisoning by it, the blood in the left ventricles of the heart is generally found black.

There are two remarkable cases in the Dictionary of Practical Medicine and Surgery, in the article “Apoplexy,” by Cruveilhier, of the effects of opium in cerebritis. One, a woman with hemiplegia, 78 years of age, who experienced in the upper paralyzed extremity, violent shocks, during which the hand struck the breast with great violence, producing the most painful contractions, and accompanied with loud screams. He tried opium internally, having found every other remedy useless, and the pains were instantly calmed. The other case is when the pain in the paralyzed limb was so severe that nothing but opium afforded the slightest relief. There is another interesting case recorded by Valisnieri. A jealous man administered to his concubine a large dose of cantharides, with the intent of destroying life. The stomach and intestines instantly became the seat of excruciating pain, accompanied by the most heart-rending cries, when, with the intent of giving her a *quietus*, the monster gave her two drachms of solid opium. The woman slept soundly for three days, at the expiration of which she woke, free from all pain.

Some of our standard works abound with illustrations of the value of this drug, even in acute diseases. Cullen and Lieutaud both assert that no medicine is to be compared with it in checking the paroxysm of pyrosis. Sydenham,

too, in his own aphoristic way, tells us that, *sine illo, manca et claudicet medicina*. Huxham and Sarcone gave it in pneumonia. Barras states that nine out of ten of Broussais' gastro-enterites are best combated by it, as irritation, not inflammation, is the disease.

Much of the obscurity which shrouds the operation of this medicine, and the class of narcotics in general, is owing to the opposite and contradictory opinions advanced by writers on this subject, few, if any, of which, are the result of inductive reasoning. When allaying pain, we find them described as anodyne; sedative when checking the rapid flow of humours; and hypnotic when producing sleep. One class objects to opium in incipient inflammation, from a belief that it quickens the action of the heart and arteries; others as stoutly assert that it produces the opposite effect. Some, again, account for its effects by dividing its properties into two classes—stimulant, which acts first; and then sedative: whilst some of the French school assert that its action is neither sedative nor stimulant, but what they denominate—*perturbatrice*. Opinions like these are sufficient to shew that we have yet much to learn on this subject.

The dread of its poisonous properties has excluded its administration in many cases, where a free use of it would in all probability be attended with marked success. We have cases where 1500 grains were taken in seventeen days; and where twenty ounces of laudanum had been taken in twenty-four hours, without destroying life. The opium-eater took daily 8000 drops.

In the case of children I confess myself unable to offer a satisfactory explanation of its operation. We know that its exhibition has been attended with fatal results, in the case of infants, even in the small dose of three drops; so that in our present state of knowledge as regards the different preparations of opium, we must, in the case of infants and children, use it with the caution which their tender age and helpless condition demand.

CASE OF FEIGNED PARTURITION;

WITH REMARKS ON THE PROOFS OF DELIVERY AND INFANTICIDE.

To the Editor of the Medical Gazette.

SIR,

If the following cases, with remarks, seem to you sufficiently interesting, be pleased to give them a place in your excellent journal, and favour

Your obedient servant,
J. B. THOMSON.

Alva, Oct. 28, 1836.

Aug. 9th, 1836.—This day I was consulted by —, to ascertain whether or not his wife, from whom he had lived apart for the last eight months, had given birth to a child, as was reported. The husband stated, that about fifteen months ago he married rather against his better judgment, but was driven to do so in consequence of his wife, the object of the present investigation, setting forth that she was with child by him. This proved to be an imposition. In about three months after marriage she again gave out that she was in the family way, took to her bed, shewed all the signs of a miscarriage, and actually imposed upon the surgeon who was then called to attend her. In consequence of these instances of duplicity, and divers malpractices, — — says he left his wife about eight months ago. This morning he is informed, on her own authority, that she bore a child at one o'clock A.M., which died in two hours after; and upon this fact he requires medical testimony. He not only doubts his wife's word, but says another reason for not believing in her having borne a child is, that he never knew her to be as other women are—i. e. having menstruation.

Without delay I called on Mrs. —. I found her a good-looking person, turned of 30 years of age, who, with clean cap, white bed-gown, and white sheet covering the bed-clothes, appeared as women are accustomed to do *en accouchement*. Her face had the ruddy hue of high tonic health, perhaps coloured with a degree of shame and confusion.

With some difficulty I persuaded her to submit to my inquiries, and answer a few plain questions, and insisted that, for the sake of allaying public clamour, it was quite necessary medical evidence should be had in her case. I remonstrated with her, shewing that if there was any truth in the report of her having borne a child, that she had exposed herself to judicial inquiry, since she had not called adequate assistance; and, moreover, I could satisfy myself by a short investigation whether her story was true or not. In fine, I recommended her at once to tell the truth, for her own sake and that of all concerned. By this time she allowed me to lay my hand upon her breasts and belly, &c. She now became alarmed, and confessed that there was no child born. She said that she had not any menstrual discharge for twelve months before; that she gradually enlarged in consequence, until she and all the neighbours believed her pregnant, and through the night she had a fearful discharge of blood, &c., with something substantial, which was thrown out by an attendant. I then pointed to a coffin for an infant lying on the table, and asked what was the use of this if her story was correct. The husband was now brought into the room, who said that a child, or something like one, had been laid out upon the table some time ago, but that his wife had taken it into bed with her, and concealed it among the clothes. He put his hand among the bed-clothes, and brought out a miserable imitation of a child, being a bundle of rags, with a stick or two to give the shape consistence! The object of all this *ruse* was to procure money from the husband.

The most important part of the foregoing case is the plausible story of the woman, that she *had not any menstrual discharge for twelve months before; that she gradually enlarged in consequence, and through the night she had a fearful discharge of blood, &c., with something substantial, which was thrown out by an attendant.* The confession afterwards, and the subsequent disappearance of the woman, hindered me from satisfying myself as to the truth of the foregoing story; but had she not confessed, and the statement proved true,

there would surely have been very considerable difficulty in this investigation. Had it been true that the accumulation of menses for twelve months that morning appeared, and brought away something substantial, almost all the valid signs of delivery might have been present, and led astray the medical inquirer.

It is well known that the state of the abdomen after delivery may be simulated after it has been recently distended, by many causes, as hydatids, dropsy, atrophy, and, as was possible in the present case, accumulated menses. After such diseases we should find a loose and flaccid belly, a soft and full and tumid state of the vulva and external organs of generation, enlarged uterus, patulous os uteri, laceration of the fourchette or perineum, and even a discharge not easily distinguished from the lochia, independent altogether of delivery of a child. As to the *mammæ* and other appearances, they are often of a very delusive and unsatisfactory nature as proofs in a case of much moment.

From these observations we learn that few subjects demanding medical testimony are more involved in doubt and difficulty than inquiries into the proofs of delivery. Happily for the honour of the times in which we live, the spirit of attention and philosophic investigation has been especially directed to this important branch of judicial medicine. The ingenuity of our own profession, which has never been proverbial, and that of the law, which has always been so, have shed much additional light on such topics. The result has been, that what a few years ago was accounted most unequivocal evidence on some medico-legal cases, has of late been scouted at as matter of great uncertainty; and where not a grain of doubt was cast into the opposing scale, a weight of new facts has equipoised, or completely turned, the balance of justice on the side of the accused. Not less uncertain are the proofs of infanticide, with a remark or two on which subject I shall close this communication. The following cases lately came within my own knowledge.

Mrs. B. was suddenly taken with labour when sitting at the breakfast-table with the other members of the

family. She speedily arose from the table, and made for her bed ; but before she could reach it, and before medical assistance arrived, a fine child was born. She was yet upon her feet, and the child being unattended to, fell upon the floor, and was taken up by the surgeon, when he arrived, quite dead.

Mrs. H., a worker in the Devon Colliery, while in the pit, and at a distance from help, was suddenly taken in labour, and bore a child alive ; but it died before any one arrived to assist her.

Cases like these are by no means uncommon, and certainly ought to be kept in mind by medical men, when called on to give evidence in a case of suspected infanticide. With respect to *appearances of violence*, it behoves the examiner to exercise the strictest caution, both as to the facts detailed, and the inferences deduced therefrom. Injuries to the body, and crushing of the cranial bones, it is clear, could not be accounted satisfactory evidence that a child had been voluntarily destroyed, unless borne out by more important and collateral proof. Swellings of the soft parts, bruises, crushing of the bones, and even fracture, may occur in circumstances where the mother perhaps denies herself the assistance which would be desirable, or is suddenly taken in labour, and no aid can be rendered.

Strangulation has ever been held as a process most likely to be resorted to, and well suited to accomplish the destruction of an infant. But a suspicious case, attended by an unskillful person, lately came under my notice, where the child was strangled by the umbilical cord about the neck. Children are very often born with the umbilical cord about their neck, and therefore any evidence drawn from appearances of strangulation must be precarious and uncertain.

Perhaps the publication of these remarks may be useful, in shewing the uncertainty attending the proofs of delivery and infanticide.

[We should be glad to be favoured with the particulars of the case to which our correspondent alludes—"where the child was strangled by the umbilical cord about its neck." Instances of death produced in that way have been considered rare.—ED. GAZ.]

OBSERVATIONS
ON THE
COMPARATIVE ANATOMY OF THE
MUSCLES AND NERVES OF
THE EYE-BALL,

AND ON THE THEORY OF THEIR FUNCTIONS,
PROPOSED BY MESSRS. HUNT AND
WALKER.

BY JOHN THURNAM, M.R.C.S.

IN making a few observations upon the subjects embraced in the title of this paper, I would wish to observe, that it is to the explanation of the functions of the nerves and muscles of the eye-ball, given by Mr. Walker in a paper published by him in the *MEDICAL GAZETTE*, for September the 24th, that I refer throughout. I think it, however, only fitting to place the name of Mr. Hunt, in conjunction with that of Mr. Walker, as, according to the admission of the latter gentleman, his theory is based upon an original suggestion of Mr. Hunt's.

The theory of the functions of the nerves and muscles of the eye given by Mr. Walker must, I think, be generally admitted by physiologists as, at the least, much nearer approximating to the truth, than any hitherto proposed. I have the greater pleasure in making this avowal, in consequence of having on a former occasion been opposed, and on that subject I still am, to the views of Mr. Walker*. In order, however, to the full establishment of any physiological theory, it is not, I think it will be admitted, sufficient merely to prove that it is consonant with the anatomy of, and with the result of experiments upon, the organs concerned, in the healthy adult human subject. The physiologist ought in all cases to be prepared also to shew that his theories are all, at the least, repugnant neither to any facts observed in the gradual development and growth of such organs, from their earliest appearance in the embryo, to their attaining their full maturity in the adult form ; nor yet to a consideration of the human organism in either an original or an accidental abnormal condition. Lastly, the theory should, *mutatis mutandis*, be likewise applicable to the explanation of the functions of the corresponding

* *MEDICAL GAZETTE*, vol. xiii. p.p. 864, 971.

organs in the lower animals. It may, I believe, be safely affirmed, that physiology has been too long studied in reference to but one object of its domain—man; and that from this one-sided pursuit of the science, numerous false doctrines have been, and still continue to be, promulgated, which, under a more extensive view of the matter, would never have been propounded. In physiology, too long have we neglected the celebrated axiom of Bacon,—“*Omnium gravissimus error in deviationem ab ultimo doctrinarum fine consistit.*”

It is in a portion of that spirit of investigation that I thus venture to recommend to others, that I am desirous of making the ensuing remarks upon the functions of the nerves and muscles of the eye-ball.

It is well known to comparative anatomists, that in addition to the six muscles of the eye-ball met with in man, there exists, in all mammiferous animals, with the exception of the quadrumania, another muscle, which arising from the bottom of the orbit around the optic foramen, passes forwards, surrounding the optic nerve, and is inserted into the sclerotic coat of the eye, a little behind the attachment of the tendons of the four straight muscles. This muscle varies in form and arrangement in different animals. In the ox, as in other of the Ruminantia, it forms a kind of muscular tube or funnel around the optic nerve, and after a short course, partially separates into two fasciculi, one of which, double the size of the other, is situated internally and superiorly; the other externally and inferiorly. These two fasciculi are inserted into a circular line on the sclerotic coat, about three lines behind the attachment of the recti. In the dog, again, as in the other Carnivora, the muscle has the same origin, but divides at an early part of its course into four fasciculi of equal size, which are connected with each other laterally, by a delicate aponeurosis, and are inserted into the sclerotic coat, at four equi-distant points, intermediate to, and a line or two behind the insertion of the four proper straight muscles of the eye. This muscle is met with in the turtle, and in most, if not in all, the Reptilia and Amphibia; it is absent in fishes, and in birds its place is occupied by the *musculus quadratus* of the nictitating mem-

brane. It was familiarly known to the earlier anatomists, some of whom, as Vesalius, erroneously attributed it to man; and it is generally known under the name of the *suspensorius* or *retractor oculi*. It constitutes the “*musculus septimus brutorum*” of the English anatomist, Willis, and is the “*muscle choanoïde*” of Cuvier. Willis, in his work “*De Anima Brutorum**,” gives the following explanation of its function:—“*Observare est quod quadrupedes, qui oculos in terram pronos, ac pendulos gerunt, musculum peculiarem habent, quo oculi globus suspenditur, et, ne pondere suo extra ossis orbitam dilabi aptus sit, sustentetur.*” This explanation of the function of the muscle is also adopted by other anatomists; but on the other hand, there are some who attribute to it, not so much of a general suspensory action as an occasional retracting one, and by the latter it is generally spoken of as the *retractor* muscle of the eye. I incline myself to believe that it is seldom called into active voluntary contraction in such a way as to produce a powerful retraction of the ball of the eye; an action in which I should suppose it to be only subsidiary to the four straight muscles of the eye. I shall hereafter assign a reason for this conclusion, viz. that the eye in quadrupeds is suspended by the ordinary and uniform degree of contraction of the seventh muscle.

Although the muscles of the eye appear to have been well examined by our modern comparative anatomists, yet it is to be regretted that the nerves supplying them should have been comparatively neglected; for I do not find that any modern author states the nerve which the suspensory muscle receives. It is, at the least, not named in the works of Cuvier, Blumenbach, Carus, Fyfe, or Grant. *A priori*, probably, it would have been expected that its nervous supply would have been derived from the common motor nerve of the eye, of the third pair. It is, however, supplied by a division of the abductor nerve of the sixth pair; and this would appear to be a universal fact, for I have found it to be thus in the Ruminantia (ox and sheep), the Solipeda (horse), *Pachydermata* (swine), and Carnivora (dog), amongst Mammalia. The distribution

of the sixth nerve to the suspensory muscle is, so far as I know, mentioned only by one modern author, and that is in relation to the Chelonian reptiles, by Bojanus, in his splendid monograph, "*Anatome Testudinis Europææ*."

What is a singular circumstance in the anatomy of the sixth nerve in the Mammalia is, that although of the two muscles to which it is distributed, the suspensory is double the size of the abductor, yet that it gives a much larger proportion of its filaments to the latter. In the various eyes that I have dissected, I have uniformly noted that two-thirds, or even three-fourths of the filaments composing the sixth nerve, are given to the abductor, and only the remaining third or fourth to the suspensory muscle. This circumstance, I think, is sufficient strongly to support the view of the function of the latter muscle, which I have taken above.

When I first noticed this fact in comparative anatomy, I was not aware that there was any published account of it; and two years since, when I had the pleasure of attending Mr. Mayo's lectures on the anatomy and physiology of the nervous system, I took an opportunity of pointing it out to that gentleman as a fact apparently opposed to his explanation of the functions of the nerves and muscles of the orbit*. I have since found, however, that the comparative anatomy of the sixth nerve was well known 150 years ago to Willis, from whom I quote the following:—"Nervus iste (conjugationis sextæ) antrosum tendens, prope oculi orbitam in duos ramos dividitur; quorum alter in musculus oculi abducentem, in exteriore ejus anguli situm, inseritur; atque alter in varias fibras diremptus, musculo septimo, brutis proprio, impenditur, adeo ut hic etiam nervus oculi motibus, fere tantum patheticis, aut ab instinctu naturali excitatis, inservire videatur†."

Willis likewise concludes, that the fourth pair of cerebral nerves, to which he gave the name of *pathetici*, as well as the sixth, are involuntary nerves; and that the voluntary motions of the eye are all performed by the muscles supplied from the third pair. He thus anticipated the views of Sir Charles Bell upon this question—views, how-

ever, which, like the theory of a respiratory system of nerves, of which they form a part, cannot, I think, be regarded as satisfactory, and to which there appear to be insuperable objections.

I would here submit, that before we ought to regard the theory of the functions of the nerves and muscles of the eye proposed by Mr. Walker as established, we ought to be able to show that it can be reconciled with the fact of the suspensory muscle in the lower animals being supplied by the sixth nerve. Mr. Walker will, I am sure, agree with me in considering it highly desirable to subject his theory to every test capable of being applied to it; and more especially when we recollect that with its adoption is necessarily connected the rejection of two theories on the same subject, propounded by such distinguished physiologists as Sir Charles Bell and Mr. Mayo—theories, however, which, it must be observed, cannot be regarded as having the same claim to attention that the one proposed by Mr. Walker has, inasmuch as they neither of them attempt to give a complete explanation of the nerves and muscles of the eye; the one of them, that of Sir Charles Bell, offering no explanation of the abductor muscle having a distinct nerve; and the other, that of Mr. Mayo, leaving the question of the superior oblique muscle, and the fourth nerve, equally in the dark.

In relation to one of the disputed points involved in this discussion, I may observe that in two dissections of the muscles of the eye of the ox and dog, made since the publication of Mr. Walker's paper, I have noticed that the insertion of the two oblique muscles is decidedly anterior to the vertical axis of the ball,—a fact confirming, I think satisfactorily, the view which Mr. Walker takes, in common with Meckel, Cloquet, and Knox, of the action of these muscles, in opposition to the reverse doctrine of Albinus, Bell, Mayo, Dalrymple, and others.

Although I have bestowed upon this subject considerable attention, and some reflection, yet I have not been able to perceive the necessity for any peculiar consent or sympathy between the suspensory and abductor muscles of the eye of quadrupeds. Mr. Walker, however, or some other physiologist, may perhaps be able to point out such a con-

* Vide Mayo's Physiology, second edition, p. 394.

† Nervorum Descriptio et Usus, cap. 22. p. 78.

nexion; and will probably be kind enough to answer the query with which I shall conclude these very cursory observations—*Is the fact of the suspensory muscle of the eye in the lower animals, being supplied by the sixth nerve, reconcilable or not with the explanation of the functions of the muscles and nerves of the eye ball, given by Mr. Walker?*

Westminster Hospital,
Nov. 2, 1836.

ON THE
OPERATIVE PROCEEDINGS
REQUIRED FOR
THE REMOVAL OF THE DISLO-
CATED LENS.

BY RICHARD MIDDLEMORE,
Surgeon to the Birmingham Eye Infirmary.

IN addressing to you some further observations on the operative measures required in certain varieties of dislocation of the crystalline lens, I shall offer no hackneyed apology for what may be considered the limited and very sectional character of my remarks, inasmuch as it appears to me that the *elaboration of the details* of medical and surgical subjects is one of the most legitimate and important objects contemplated by the establishment of medical journals; for in what other vehicle of information can the various objects of medical inquiry be investigated with equal minuteness? If the author of an ordinary octavo volume attempt this *elaboration of detail*, it is not difficult to predict how large a part of the projected matter of his work will remain unaccomplished. Regarding, therefore, medical journals as depositories of information the most ample and exact, and of inquiry the most elaborate and extended, I have, in my various communications to the GAZETTE, frequently selected, for investigation, a part of the section of a subject (if I may be permitted so to speak) which, if it has not instructed, has at least fatigued somewhat less than if a prolonged investigation of a large and comprehensive subject had been entered upon in the same manner in respect to all its parts. It appears to me that every practitioner should be encouraged to come forward, and deposit his stock of useful knowledge as he

gradually acquires it (and who is there who can practise our profession without acquiring some portion of information worth communicating to others?) in a place which we have endeavoured to represent as being peculiarly adapted to its reception, so as to supply to the actively intelligent and devotedly industrious, an opportunity of aggregating the information comprised in the scattered labours of many writers, in a condensed and readily accessible form. In short, every man should feel it to be his duty to furnish some part of the materials, at least, of that rising fabric which the more diligent and enlightened will eventually fashion into a storehouse of professional knowledge—a temple of medical science, of a construction so perfect and beautiful that the finite faculties of man can scarcely further improve or adorn it. To approach even this typified perfection of knowledge, the active and constant exertions of all are required.

The practice of removing the lens, when displaced into the anterior chamber by accidental violence, or from other causes, has been long known, but not, until lately, so much acted upon as, I think, it ought to have been. Daniel mentions, that “M. Petit a pratiqué, en 1708, la section de la cornée pour extraire le cristallin qui était passé dans la chambre antérieure*”; and Dr. Warren has furnished an elaborate and able article upon the subject†, in which he appears to consider that it is not only necessary to remove the displaced lens by an operation, when it has already produced acute inflammation of the eye, but that it is also justifiable to extract the lens immediately after it has become displaced, as a means of preventing the occurrence of severe inflammation. I do not, however, intend to point out the forms of dislocation which more especially require the performance of the operation, nor the period, after the occurrence of the displacement, at which it would be desirable to operate; for these things have been already fully discussed‡. My chief object is to di-

rect attention to the mode in which the displaced crystalline should be removed, in those cases where from its constant or occasional residence in the anterior chamber, or in whatever situation it may be placed, such operation may be deemed requisite. If, then, it be necessary to extract the displaced crystalline through an incision of the cornea, should that incision be made at its upper or lower part? Before replying to this question, it is proper to inquire into the usual state of an eye in which a dislocation of the lens into the anterior chamber (for it is to this form of accident, or disease, that my remarks are more especially intended to refer) has recently occurred. We find that the eye is more or less inflamed—that its muscles, and those of the eye-lids, are irritable and spasmodic in their action—and that there is great intolerance of light. If an attempt be made to raise the upper eye-lid, the orbicularis muscle acts with great power; the surface of the eye is exposed with considerable difficulty, and the patient suffers extreme pain. Having, however, made a section of the upper part of the cornea, varying in size in correspondence with the magnitude and density of the lens, it is found to be amazingly difficult to introduce a hook for the purpose of removing the displaced crystalline: to introduce a hook through an opening at the upper part of the cornea, for the purpose of extracting a lens situated at the lower part of the anterior chamber, in an eye already much inflamed, is, I repeat, a matter very difficult of performance, and hazardous of execution. Skill and tact may accomplish it, but I entreat my professional brethren to witness the comparative ease with which a different mode of operating may be practised, before they resolve on making such extraordinary demands on their operative dexterity.

If the incision be made at the lower part of the cornea, and the knife be carried, as it ought to be, behind the solid (if soft, it will not require extracting) lens, it is then prevented from retiring behind the iris, and no efforts at removal are necessary; for the crystalline generally passes through the corneal opening without any trouble whatever.

The preceding method of operating has been recommended in my work*,

and I should not so soon have referred to the subject again if I had not had a recent opportunity of observing the difficulties encountered by an excellent surgeon, in consequence of pursuing a different practice, and of ascertaining, by conversing with various professional friends, that they are prepared to give the influence of their recommendation to this, as I conceive, very mischievous and erroneous surgical practice: for it cannot escape observation, that the evils to be apprehended arise not so much from the mere section of the cornea as from the manipulations required, and the injury inflicted by the attempts to remove the lens.

NOTICE

OF A NEWLY-DISCOVERED

PECULIARITY IN THE STRUCTURE OF THE UTERINE DECIDUA, OR DECIDUA VERA.

By W. F. MONTGOMERY, M.D.

Professor of Midwifery to the King and Queen's
College of Physicians in Ireland*.

It would be an unprofitable occupation of the time of the Association to enter into any thing of a general or detailed account of the structure and relations of the decidua, which are so familiar to the profession. I shall, therefore, take for granted that my hearers are in full possession of the different points already well known on this subject, and confine myself exclusively to a brief notice of a peculiarity in the structure of this product, which, as far as I am aware, has never been described, although perhaps one of its most important and interesting features. About four years ago, while preparing the component parts of a human ovum, in the third month, for lecture, I observed that when the decidua vera was immersed in water, with its uterine surface uppermost, there appeared amongst the floating and shred-like processes which covered it, certain small circular openings, which at first I took to be merely foramina in the membrane; but on attempting to pass the point of a fine glass rod through one of them, I found it to be a cul-de-

sac. Being thus incited to ascertain how the matter really was, and examining carefully then, and having repeated the examination frequently since, I have fully satisfied myself and others who have examined the part with me, or to whom I have exhibited it in my lectures on embryology, both of the existence and peculiar character of the structure about to be described. There are on the external or uterine surface of the decidua vera a great number of small cup-like elevations, which project from it like little bags, the bottoms of which are attached to, or embedded in the substance of, the decidua: they then expand or belly out a little, and again grow smaller towards their outer or uterine end, which is, in by far the greater number of them, an open mouth, when separated from the uterus: how it may be while they are adherent, I cannot say. Their form is circular, or very nearly so; they vary in diameter from one-twelfth to one-sixth of an inch, and are elevated to about one-twelfth of an inch above the surface to which they adhere*: in the way of comparison, I would say that they were miniature representations of the suckers of the cuttle fish. They are not confined to any one part of the decidua, but are usually most numerous and most distinct in those parts of it which are not connected with the capillary rudiments of the placenta, and at the period of gestation which precedes the formation of the latter (the placenta) as a distinct organ: hence the best time for examining them is up to the third month. In the advanced periods of gestation they are not to be found; at least I have not seen them then. I am ready to confess at once, that I am not prepared to offer any decided opinion as to the precise nature or use of these decidual cotyledons, for to that name their form, as well as their situation, appear strictly to entitle them; but from having on more than one occasion observed within their cavity a milky or chylous fluid, I am disposed to consider them reservoirs for nutrient fluids, separated from the maternal blood, to be thence absorbed for the support and development of the ovum. This view appears strengthened when we consider, that at the early pe-

riods of gestation the ovum derives all its support by imbibition, through the connexion existing between the decidua and the villous processes covering the surface of the chorion.

CASE OF
POISONING WITH ARSENIC;

RECOVERY, AFTER HALF AN OUNCE HAD
BEEN SWALLOWED.

BY DR. JACOB T. B. SKILLMAN,
Of New Brunswick, N. J.

I WAS called to see Jane B., a native of this place, aged 22 years, at eight o'clock in the morning of the 27th of April, 1836. On my arrival, I was informed by her mother that she had taken sixpence worth of arsenic, or half an ounce, as I afterwards learned from the apothecary who sold it to the patient. Her mother handed me the papers in which it had been put up, and which showed very evident marks of having contained the poison, from the colour left upon the inside paper. She informed me her daughter had taken the whole dose the preceding evening, about twilight; that it soon produced emesis and catharsis, which continued frequent through the night. On examination, I found her pulse 140 in a minute, and irregular; she complained of much pain in her head, throat, and stomach; fauces appeared much swollen and red; eyes considerably inflamed; frequent sighing. Although somewhat reduced and exhausted by the action of the poison upon the stomach, I immediately took from her arm about twenty ounces of blood, which I thought had some effect in producing more regularity in her pulse, and would perhaps reduce the inflammation of the alimentary canal. I was also informed that her dejections appeared to contain a considerable quantity of the poison, in an undissolved state. I directed, after bleeding, an ounce of castor oil every third hour, and a wine glassful of a solution of Epsom salts in a quart of soapsuds, every intervening hour, until it should act freely upon the bowels; this last solution to be given lukewarm.

At six o'clock P.M. I found that she had rejected the most that she had

* An accurate engraving of these decidual cotyledons will appear in a work on Pregnancy, now on the eve of publication.

taken, and that the operation upon the bowels was very scanty; pulse more frequent; complained of more pain in the stomach. Ordered the medicine in smaller doses, and to be continued through the night until it should produce the desired action upon the bowels.

At eight A.M. on the 28th, her bowels had been freely acted upon by the medicine; stomach appeared less irritable; complained of more pain in the fauces, throat, and stomach. I prescribed leeches to the throat and stomach.

At six P.M., pulse more frequent, and an ash-coloured appearance of the centre of the tongue; edges much reddened by inflammation; complained of much pain throughout the system, with great and incessant itching of the skin; some tenesmus and strangury. Directed her to take a solution of tart. antim. and sp. nit., a tea-spoonful every hour, until the excitement abated; toast water and barley water for drink.

At 8 A.M., 29th, appeared somewhat relieved of all the unpleasant symptoms, and had eaten half a cracker. Directed a dose of salts, and a continuation of the solution of antimony.

At 6 P.M. salts had not operated: symptoms more aggravated. Directed a repetition of the salts, and a continuation of the antimony.

At 8 A.M., on the 30th, all the symptoms much more favourable; had eaten a cracker. Toast water and barley water continued for drink, and continuation of the antimony.

May 1st, at 8 A.M., symptoms the same as the previous day: had had a very restless night: drops began to act freely upon the bowels.

2d. At 8 A.M., has had a comfortable night compared with the former: tongue appears cleaning: has eaten some oyster soup.

3d. At 8 A.M., appears still more comfortable: sits up part of the day, and appears convalescent. She now complains only of debility and soreness of the tongue: her lower extremities appear somewhat œdematous, and her pulse is still frequent, but soft and elastic.

30th. She is now enjoying her usual health*.

ANALYSES AND NOTICES OF BOOKS.

—
 "L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALMBERT.
 —

Darstellungen und Ansichten zur Vergleichung der Medicin in Frankreich, England, und Deutschland. [A Comparative Sketch of Medicine in France, England, and Germany.] Von Dr. ADOLPH MUEHRY. Hannover, 1836. Schloss.

DR. MUEHRY'S tour took place in 1835, and the notes made on the occasion have formed a very respectable pocket volume, which strangers from Germany will find useful as a guide. Correct maps of London and Paris are subjoined, having the chief localities interesting to the medical visitor conspicuously marked upon each. The account given of our hospitals is, generally speaking, correct, or at least there are no material errors in it, which, perhaps is as much as can be expected from a tourist making one or two flying visits.

—
Historisch-kritische Darstellung der Theorien über das Wesen und den Sitz der psychischen Krankheiten. [Account of the several Theories which prevail, respecting the Nature and Seat of Mental Diseases.] Von Dr. J. B. FRIEDREICH. Leipzig, 1836. Schloss.

This is an extremely interesting work, displaying all that erudition and practical experience through which Professor Friedreich has long since attained so distinguished a name. The subject is lucidly treated under the respective heads of the material, immaterial, and the mixed theories, with critical remarks on the principal supporters of each. The views of Jacobi and Combe are discussed; also those of Heinroth, Harper, Groos, and other authors of reputation: and on the whole, we have such an account presented to us of the actual state of medico-psychological literature, as we should be glad to see transferred into our own language. It would serve, we think, materially to promote in this country the study of a branch of medical science which has been but too much neglected—we mean that of mental diseases.

—

Dr. Gustav Blumröder über das Irre-seyn, oder anthropologisch-psychiatrische Grundsätze [Dr. Blumröder on Insanity]. Leipzig, 1836. Schloss.

In this brochure, Dr. Blomroeder has attempted to treat the subject of insanity in a popular manner, or at least as well for the non-professional as the professional reader. He gives an account of the unity (*einheit*) of man, of the blood, the brain, and spinal marrow—of the two great faculties of the understanding and the will—of the various kinds of mental unsoundness, imbecility, melancholy, eccentricity, delirium, insanity; with views of the etiology, diagnosis, prognosis, the treatment and pathological anatomy of mania. The author's great resources of learned experience shine throughout; but how far his book would be popular here, even if it were translated into English, is questionable. It is dedicated to Professor Friedreich.

Analekten über Kinderkrankheiten. Heft. i.—viii. Stuttgart, 1834-6. Schloss.

This is a collection of papers on the diseases of children, which appears periodically, and is designed for the use of German practitioners. The contributors are of all countries; many of them French, American, and English.

Encyklopädie der gesammten Medicinischen und Chirurgischen Praxis. [Cyclopedia of Practical Medicine and Surgery]. Von Dr. G. F. Most, &c. Heft. i.—v. Leipzig, 1836. Schloss.

It is intended to complete this Encyclopedia in twelve *hefte*, forming two octavo volumes; and a valuable work it will be, if we may judge from the portion (nearly the half) which is before us. It abounds with information on the several topics which are treated, and the literature is rich to profusion. The arrangement is alphabetical.

Der Mensch nach den verschiedenen Seiten seiner Natur, oder Anthropologie, &c. [Man variously contemplated, &c.] Von Dr. K. F. Burdach. Stuttgart, 1836. Schloss.

Professor Burdach here offers to the "educated portion of the community,"

a popular physiology, executed in a manner worthy of his distinguished abilities. It is to be completed in five parts, two of which have appeared—the first treating of organic, and the second of animal life.

Die Leistungen und Fortschritte der Medicin in Deutschland im Jahre 1834. [Progress of Medicine in Germany during the year 1834.] Von Dr. M. J. BLUFF. Berlin.

WE last year gave an account of the first two volumes of this work, and have been anxiously expecting the appearance of the continuation. The volume now published only brings us to the close of the year 1834; but every allowance must be made for the author of such an undertaking, when we consider that he not only gives us an account of all the new works, and new editions of works, brought out in Germany during the year, but a notice of all the articles published in the periodicals, arranged under their respective heads! The two indexes of names and subjects, which are added, render the work perfectly accessible in the way of reference.

Medical Study; an Introductory Address delivered at the Bristol Medical School. By J. A. SYMONDS, M.D.

WE have perused this Address with much pleasure; it contains a great deal of valuable advice within a moderate compass, and displays the author's taste and good sense throughout. Some extracts we should be glad to transfer to our pages did our space permit; for only one can we find a corner. The author eloquently advocates the claim of our profession to be considered, as in this country it has long been, a learned one. He discourages, however, the mass of students from discursive literary pursuits, recommending in preference a concentration of their talents upon some well-defined object. "To the many," says Dr. Symonds, "I address myself; to those who with good average understandings wish to fit themselves for their future duties; and to such I would say: Beware of frittering upon a multitude of objects, talents which, prudently economized, may make you wise in your generation, and useful to many generations to come. Medical science is not what

it was in former times, nor is, indeed, any science. Look to any one of the physical sciences, and observe the division of labour. Take natural history: for one Cuvier, who commanded all its departments, what numbers you discern, distinguished indeed, but distinguished only in particular branches. How well, then, might we expect, *à priori*, that medicine must demand, from ordinary minds, an attention all but undivided. How much stronger also must this view become, by reflecting on the practical duties, cares, and distractions, which the application of medical science involves!"

MEDICAL GAZETTE.

Saturday, November 12, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

HOMŒOPATHY

SKETCHED IN ITS OWN COLOURS.

THE homœopaths say that they are not rightly understood,—that their doctrines are misrepresented,—and that they have not had a fair hearing. Poor innocents! We shall try whether we cannot aid them in becoming better known to the public. But lest we too should be subjected to the charge of mis-stating, we think it right to premise that we shall simply read a leaf out of their own book—make, in fact, a few selections from a prime production of the great Master himself—and offer a few plain comments, to impress their importance the more strongly on the minds of our readers.

Every body knows, or ought to know, that homœopathy abhors unpleasant doses of physic: that is to say, the homœopathic *doctors* never administer so much as a grain, for instance, of any medicine; they go to work with the millionth, or fraction of a millionth, of that quantity,—which no doubt is a potent recommendation of them to many

people who hate the taste of drugs. But we apprehend that the world is not sufficiently aware of the miraculous effects of these invisible doses; which, indeed, seem to be the more wonder-working the more infinitesimal and spiritual they are rendered.

Let us take an example. The vulgar medical world—styled by the disciples of Hahnemann, *allopaths*—have long thought that there were many substances which, though still retained in our pharmacopœias, were inert, especially when exhibited internally. This the homœopaths have discovered to be a mistake. Charcoal, for example, which had often been tried medicinally, and given even to the extent of a pound in the day, without other effect than that of passing out of the body unaltered as it went in, has proved in the hands of the "revivers" of medicine to be a substance of most thaumaturgic qualities: the millionth of a grain of charcoal has given rise to astonishing symptoms.

In the *Materia Medica* of Hahnemann—even in the condensed French translation by Jourdan—no less than forty-six octavo pages are devoted to the detail of the symptoms produced by charcoal in doses not exceeding the millionth of a grain. *Seven hundred and twenty* is the number of symptoms ascribed to this dose of vegetable charcoal (*carbo ligni*), while *one hundred and ninety* are attributed to the same quantity of *carbo animalis*. In other words, the $\frac{1}{5,760,000,000}$ of a dose which has been found perfectly inert, is described as producing 720 symptoms!

But let us see what are those symptoms. Here are some specimens almost taken at random: and we pray the reader to keep steadily in his mind that the person or persons who have experienced these symptoms have taken the *maximum* dose of the millionth of a grain of *charcoal*—charcoal made of any kind of

wood; for Hahnemann says it is not material from what kind of wood it is made.

84. The face itches, particularly about the eyelids.

85. The inner angle of the *left* eye itches. (*Gersdorff*.)

86. A sensation of smarting itchiness, particularly in the external angle of the *right* eye. (*Idem*.)

87. Itching in the left eye; the part smarts after being rubbed, particularly at the inner angle.

88. A smarting in the inner angle of the left eye.

And so on for upwards of twenty more symptoms—all about the eye; or as some vulgar jesting allopath would say, “all my eye”: but this specimen may serve.

The eye, however, it appears, is not the only part that itches when we take the millionth of a grain of charcoal.

324. Itching of the anus; the part gets hot after it is rubbed. (*Gersdorff*.)

325. In the morning, while in bed, the anus itches, and gets worse for scratching: heat of the part follows. (*Caspari*.)

326. Smarting of the anus. (*Gersdorff*.)

Oh, wonderful sympathy of MM. Caspari and Gersdorff! immortal pupils of the great Hahnemann! how will posterity admire the acuteness of your sensations, and the *extreme profundity* of your remarks!

Now for another set of symptoms. Enter Messrs. Gersdorff and Caspari again, having taken their millionth dose.

299. Windy colic: flatus circulating irregularly in the bowels, more particularly towards the left side and the back. (*Gersdorff*.)

300. Rumbling in the bowels, immediately. (*Idem*.)

307. After the rumbling, *émission de vents nombreux*. (*Idem*.)

308. Rumbling in the lower bowels perceptible to the ear, *avec émission sourde de vents presque inodores, humides, et chaudes*. (*Idem*.)

309. Flatus rolling in the bowels, *et il en sort quelques unes qui sont sans*

odeur, (in the course of half an hour.) (*Caspari*.)

But Gersdorff finds that in an hour and a half the case is altered: the nose begins to perceive as well as the ear.

312. *Vents, ayant un odeur putride*.

Yet once again—

310. On awaking in the morning, *énorme émission de vents sans odeur*.

For this last observation we are no doubt indebted to Hahnemann himself: there is a boldness in the *énorme* which gives it all the *air* of a master. With due deference, therefore, for so high an authority, presuming that we have to deal with the Doctor himself, we shall very humbly submit whether he and his pupils are quite sure that these formidable *émissions de vents* are altogether owing to the charcoal. Our hesitation to believe it simply arises from this, that the experimenters while on duty are allowed to eat French beans, green peas, and carrots. (*Vide Organon*, 118.)

Now to us it appears something like an infraction of the just laws of inference, to conclude, because a man is affected with flatus after a vegetable repast, that the said flatus is due, not to the peas and beans he has devoured, but to the millionth of a grain of charcoal which has been taken some hours before. Such, however, is the ingenious reasoning of the homœopaths. Admirable logicians!

The reader perhaps thinks that there is nothing else remarkable about charcoal: but this is not the case. We have still a few other symptoms to notice.

226. Repugnance to butter.

This wonderful property belongs to wood charcoal; but the animal sort is not less remarkable.

69. The appetite becomes destroyed (*se perd*) by eating!

Here is another symptom produced by animal charcoal—

114. Upon riding on horseback, the seat gets heated, and the part blisters.

In other words, the millionth of a grain of charcoal will cause a horseman speedily to "lose leather." But to proceed :

146. The right axilla itches.

159. A wart on the finger itches.

177. Lively dreams of scientific objects : dreaming of the discussion of literary works : talking aloud in sleep.

Innocent and happy homœopathists, if these were your only dreams ! Take charcoal, ye Uwinses and ye Everests, and be happy ! But stay ; what do we see in another part, among the effects produced by this *potent* drug ? Really our readers must translate for themselves.

374. Pollution qui ébranle fortement et douloureusement les nerfs : après quoi ardeur extrêmement violente à la partie antérieure de l'urètre, et en urinant une vive douleur secante avec ardeur, &c. (*Gersdorff*.)

375. Erection continuelle pendant la nuit, sans sensations ou idées voluptueuses. (*Idem*.)

376. Absence totale de l'appétit vénérien, le matin ; *il ne peut même être excité par des idées lascives* (au bout de vingt-quatre heures).—*Idem*.

Again ; hear another worthy disciple :—

123. Pollution nocturne, pour la première fois depuis très long-temps, avec rêves voluptueux, sans érection ; après le réveil, douleur spasmodique le long de l'urètre, surtout à sa partie postérieure.—(*Adam*.)

Now only conceive all this arising "pulveris exigui jactu :—" "exigui" did we say ?—the *millionth* of a grain, and that grain of *charcoal* ! What wonder that sedate men, like the Gilchists, the Everests, and the Uwinses, men such as Hahnemann himself would have chosen for conducting his experiments, should be captivated with homœopathy. The candour, the gravity,

and the decency of the revelations above given are inimitable !

Be it always remembered, that these experiments for ascertaining the virtues of invisible doses are ordered to be conducted by such persons as we have described—men of sedate mind. Such is the precept of the great Founder. Hear the Organon :—

"The person who makes the experiment ought to avoid all fatiguing labour of mind and body, all excesses, debauches, or mental excitement, during the whole of the time that it continues. [Hear that, Master Gersdorff, you with the *idées lascives* !] No urgent business must prevent him making the necessary observations, and he must of his own accord be scrupulously attentive to every thing that passes in the interior of the body, without permitting anything to interrupt his care ; and finally, he should unite with a healthy body (in its kind) a necessary degree of judgment, that he may be able to express and describe clearly all the sensations he experiences."

Granting that the experimenters are in this high and serene state of mind and body, who can fail to be struck with the effects produced by an atom of charcoal ? Our difficulty, however, consists not only in conceding the postulate, but in allowing a particle of credit to the flatulent dreamers.

A word or two more concerning these experiments. It appears that the ladies are not allowed to be inactive disciples : we must have *their* experience too. But how this is gathered, we are not informed : whether the wives and sisters of the Gersdorffs, the Casparis, and the Adams, have been employed to observe the effects of invisible doses on their own persons, and have communicated their sensations to the father of the sect—or whether their husbands or brothers have interpreted for them, appeareth not : this only doth appear, that many odd symptoms are set down to the female experimenters. For example, dose ~~moderata~~ gr. of charcoal :

377. Forte excoriation aux parties génitales de la femme, en avant, le soir.

378. Ardeur dans les parties génitales de la femme.

379. Douleur cuisante aux parties génitales de la femme, avec flux leucorrhœique abondant, pendant deux jours, &c.

386. Flux de mucus blanc par le vagin (au bout de quatre jours).

124. From a similar dose of animal charcoal, whites at the end of a fortnight; and

125. Leucorrhœal discharge, staining the linen yellow, at the end of three weeks.

Why have we not the names of the illustrious ladies who made these revelations? why should they be cheated of their fair proportion of fame, having laboured so zealously to verify the old adage "ex carbone thesaurus?"

But enough, perhaps, of charcoal for the present. We doubt not we shall be "carbone notandi" by the Hahnemannians, for our pains. They cannot say, however, that we have misrepresented them. We have quoted their beastly descriptions given in the *ipsissima verba*, in which they express their pruriency, their flatulence, and their filth; and we have risked the displeasure of our readers by transferring so much egregious nonsense into our columns.

With reference to this last point, we can only urge in excuse, that our duty as public journalists seemed to demand that we should thoroughly expose the medical imposture of the day. We should have been spared the nauseous office, were it not for the late public circumstances which bestowed a certain degree of notoriety on the Hahnemannian delusion. It had fallen to its lowest ebb—that is to say, it was already in the embrace of certain pitiful pamphleteers, who were fast smothering it with their protection. Accident, however, or rather the mischievous bungling of one of the sect, brought the imposture again, for a mo-

ment, into notice: some of the sectaries attempted to profit by the occasion; so that they have only themselves to thank, if they now become better understood than ever. Their own foolish hands have served to tear off the veil of mystery, or obscurity, which gave them hitherto their only claim on the credulous. They pretend to want publicity and fair trial. They shall have both, if we can promise any thing within our powers of performance. And as we have shown up their impudent humbug in *charcoal* now, perhaps we may try them in *chalks*, or some other matter of that sort, on the next occasion.

COLLEGE OF SURGEONS.

By a recent regulation the Council of the College of Surgeons have determined not to receive in future the certificates of any lecturers in anatomy or surgery, who do not appear before them for examination with reference to their qualifications for teaching those branches.

BRITISH MEDICAL ASSOCIATION.

In our notice of the meeting which was recently held by the members of the British Medical Association, we expressed our regret that the card which they had the politeness to send us was not received in time for us to make use of it, so that we were compelled to take our report of the proceedings from the *Times*. The Editor of the *Lancet*, in the fulfilment of his dishonest calling, last week gave insertion to the letter of an anonymous slanderer, whose object was to produce the belief that our statement was false, and that the members of the Association regarded us with very different sentiments from those feelings of courtesy and fellowship which we had expressed towards them. Nothing, it seems, raises Mr. Wakley's bile so effectually as the idea of the General Practitioners presuming to think for themselves, and to judge of us by what appears in the pages of the *MEDICAL GA-*

ZETTE, rather than by his jealous and interested calumnies. Besides the communication which we subjoin, we have also to acknowledge the receipt of another, from an official quarter, in which anxiety is expressed to do away the impression which, it is feared, "the intemperate and unjust" letter alluded to, must have produced. We beg to assure the members of the Association that there is no risk of our connecting them with the maligners of the *Lancet*; and that this journal shall always be open to the furtherance of all measures calculated to advance the common honour and interests of our profession, from whatever quarter they may emanate.

To the Editor of the Medical Gazette.

SIR,

AT a meeting of the stewards held last night, I was directed to express to you their regret that the ticket for the late General Practitioners' Dinner did not reach you until too late to be used. This arose from the resolution desiring the attendance of reporters having only been made at so late a period as the Monday night preceding the dinner. On the whole of Tuesday I was very busy, and found it impossible to send to you, and to the Editor of the *Times*, the tickets placed at your disposal, until the evening of that day.

As the report of what occurred at the dinner, as copied by you from the *Times*, (although not incorrect), by no means does justice to our intentions, I forward to you, by the direction of the committee, a statement of the ends and objects of the British Medical Association, contained in a sketch of the plan upon which it is founded, and as read at the dinner by the chairman. Requesting that you will do us the favour to publish it in an early number of your valuable periodical,—I am, sir,

Your humble servant,

W. EALES, Hon. Sec.

Southwark, Nov. 2, 1836.

OBJECTS OF THE ASSOCIATION.

The following is a general sketch of the nature and objects of the British Medical Association:—

It is proposed, 1st, that the medical general practitioners of England and Wales shall form themselves into an Association, for the purposes of exciting and cherishing kindly and honourable feelings towards each other, and of guarding, watching over, and protecting the rights, privileges, interests, and respectability of the profession.

2dly. That the society shall be called "The British Medical Association."

3dly. That those gentlemen willing to become members, shall, at an early meeting, appoint proper officers: such as a President, Vice-Presidents, Secretaries, Councillors, Committees, &c., and shall form a code of laws for the government of the Association, to be submitted to the consideration of a subsequent general meeting.

4thly. That the Association shall hold frequent meetings for the transaction of business.

5thly. That it shall oppose all encroachments from without, and all dishonourable or unprofessional conduct among its members.

6thly. That it shall, by all legal means, or by application to parliament, if considered necessary, endeavour to remove all professional grievances, evils, and hardships.

7thly. That it shall protect its members from all illegal or unjust prosecutions.

8thly. That it shall endeavour to form a benevolent fund for the assistance of decayed members of the profession, and for the benefit of their widows and orphans.

9thly. That, to effect these important purposes, subscriptions shall be paid by the members, in such manner as shall be hereafter agreed upon, and donations requested from their friends and the profession at large.

10thly. That the Association shall endeavour to extend its expected advantages over the kingdom, by corresponding with, and inviting the co-operation of, their medical brethren in cities, towns, or local districts; and by recommending them to form themselves into societies, having the same or similar important ends and objects in view.

11th. That the members and their friends shall dine together at least once a year, in the metropolis; and that the Association shall, by all means in its power, endeavour to promote the welfare, prosperity, and union of its own body in particular, and uphold the dignity, respectability, and usefulness of the whole medical profession.

P.S.—Since writing the foregoing, it has occurred to me that it would be as well to send you an extract which was read at the dinner by the chairman, from the Address prefixed to the laws of the Southwark General Medical Practitioners' Society. As the members of that society have been principally instrumental in establishing the present Association, the following extract will tend further to elucidate their views, and to show that these

are not opinions arising out of any improper motives, or taken up to serve a purpose at the present moment merely; but that they are the deliberate opinions of honourable men:—

“It is not the object of this Society to institute or encourage a monopoly. It is intended to promote fair and honourable conduct among the practitioners at large towards each other—to encourage among them the exercise of harmony and good will—to diffuse useful medical information—to insist upon the rights and privileges vested in the members by the law of the land—to suppress illegal practitioners, and thereby protect the real interests of the public—to require the due observance of medical etiquette between the physician and consulting surgeon, and the general practitioner—in few words, to render the profession within the sphere prescribed honourable, useful, and respectable.”

These were the only objects of the gentlemen forming the before-mentioned society; and although, from the apathy of general practitioners, it was never supported as it should have been, it has gone on until the present time; henceforward it will be lost in the British Medical Association: and if this be supported, as present appearances warrant us in assuming it will be, and, I may be permitted to add, as it deserves to be, by the profession, it will confer upon all its members incalculable advantages, and prove ultimately of essential benefit to the public.

LECTURES

ON

LOCAL HYSTERICAL AFFECTIONS,

Delivered in the Medical Theatre of St. George's Hospital,

BY SIR B. C. BRODIE, BART. F.R.S.

LECTURE II.

Hysterical Retention of Urine — Aphonia — Affections of the Breast — Tetanus — Singular Affection of Hand — Sneezing, &c.

THOSE which I described in the last lecture are only a part of the local hysterical affections which fall under the observation of the surgeon, and an acquaintance with which is necessary, to enable him to practise his art with credit to himself, and advantage to the public.

Hysterical retention of urine is of

such frequent occurrence, that any particular description of it would seem to be superfluous. An observation, which has been already made, is equally applicable to this as to other forms of hysterical paralysis. The muscles are not incapable of obeying the act of volition, but the volition itself is not exercised. So it is, at least, in the first instance: but if the patient has allowed the bladder to remain for a great length of time in a state of extreme distention, actual paralysis may ensue, and she may then strive in vain to empty the bladder, without the aid of the catheter. In these, and in other cases in which the bladder has been long extremely distended, the mucous membrane becomes affected with chronic inflammation, secreting the usual adhesive mucus; and even worse consequences may ensue than these. In a case, to which I have had occasion to refer in my lectures on the diseases of the Urinary Organs, hysterical retention of urine having been for a long time neglected, at last forty ounces of urine were drawn off by the catheter. In the *post-mortem* examination, the bladder was found of a very large size, of a dark and almost black colour: there were only slight vestiges of its natural structure left, the muscular fibres being very much wasted, and the internal membrane presenting the appearance of a very thin film, which was readily separated from the parts below. The dark colour of the bladder did not seem to arise from mortification, there being no foetor, nor, with the exception of the black colour, any indication of it.

Females who labour under hysterical retention of urine, if left to themselves, usually recover in the course of a short space of time; sometimes almost suddenly: but if the catheter be employed, their recovery may be protracted for an indefinite period. We may lay it down as a general rule, that in these cases the catheter should not be had recourse to: and the only exceptions to it are in those extreme cases in which actual paralysis has taken place, and the bladder is likely to become diseased, if not artificially relieved.

Hysterical *aphonia*, or loss of voice, allowance being made for the different functions of the affected parts, corresponds very nearly to the hysterical retention of urine. It takes place suddenly, continues often for many months, even for one or two years; and then disappears as suddenly as it began. A patient thus affected may, when under the influence of strong moral excitement, find herself speaking in her natural voice, when, for some time before, she had spoken only in a whisper. Her recovery may be permanent, or she may relapse into her former condition.

This symptom is not unfrequently met with in the male sex, especially in those of the clerical profession, probably because they often lead very sedentary lives, and also because in their profession they are called upon to speak in public in a tone raised above the ordinary standard.

A tympanitic distention of the intestines is not an uncommon symptom in young women who are affected with hysteria; and, when existing to a great extent, is frequently mistaken for ovarian dropsy. The majority of cases in which the patient has been supposed to be cured of ovarian dropsy, by the agency of iodine and other remedies, have been, I doubt not, of this description. Yet the diagnosis is not difficult. The absence of fluid is distinguished by the absence of fluctuation; and the sound produced by percussion sufficiently indicates the cause of the distention. When the tumor is of a large size, there is pain in the abdomen, and the respiration is rendered difficult in consequence of the impediment which exists to the descent of the diaphragm. If the uneasiness be such as to induce the practitioner to direct the use of the warm bath, and the tympanitic distention be great, the effect is remarkable. Instead of sinking in the bath, as under ordinary circumstances, the patient floats on the surface. If an elastic gum tube be cautiously introduced, so as to reach the upper part of the rectum, and pressure be made on the surface of the abdomen, the air may, in some instances, be made to escape through the tube, until the abdomen is reduced almost to its natural dimensions: but it becomes re-accumulated in the course of a few hours. A stimulating injection, made with the *confectio ruta*, will sometimes produce the same result.

Young women are subject to an affection of the breast, corresponding to the hysterical affections of the joints, and indicated by very similar symptoms. These cases have been noticed by Sir A. Cooper, in his observations on the Diseases of the Breast. The patient complains of pain in the breast, and shrinks on pressure being made with the fingers, or even on the skin being slightly pinched. Not unfrequently the examination of the part produces twitches and motions of the body, bearing no small resemblance to those of chorea; yet if it can be dexterously managed, while the examination is being made, that the patient's attention should be otherwise engaged, not only these motions do not occur, but she may seem scarcely sensible of pain. The morbid sensibility is not confined to the breast, but extends to the axilla, and down the arm. No distinct tumor is perceptible in the breast, but when the disease has been of long continu-

ance, the whole organ becomes slightly enlarged, probably in consequence of an increased determination of blood to the small vessels; yet there is no redness of the skin, and indeed the skin is even paler than natural, with a somewhat glossy appearance of its surface.

These cases are to be distinguished from those of a rare kind of irritable tumor of the breast, of which a representation is to be found among the plates annexed to Sir Astley Cooper's work. I conceive that they ought also to be distinguished from those which may occur at any time of life, and in women who have no particular disposition to hysteria. In the cases to which I now allude, the pain and tenderness are much less than in the true hysterical affection of the breast, and it will be almost invariably found that the patient has witnessed the miseries of some friend or acquaintance who has suffered from carcinoma. No part of the body will bear that rigid scrutiny to which the breast is subjected under these circumstances. Close attention will discover in any, even in the most healthy organ, sensations which had been previously overlooked; and constant anxiety on the subject may magnify such sensations into pain. In these last-mentioned cases a strong assurance that no disease exists will make the patient happy, and remove the pain; but no such assurance will be adequate to the cure of a genuine hysterical affection.

Hysterical tympanitis is always attended with a more or less constipated state of the bowels. But obstinate constipation of the bowels is a frequent occurrence in hysterical patients, independently of any considerable degree of tympanitis; and I have known many instances in which a case of this kind has been mistaken for one of stricture in the upper part of the rectum. The surgeon here sometimes misleads himself by taking it for granted that a very long bougie may be introduced into the rectum, if there be no actual contraction; not recollecting that the naturally tortuous course of the bowel is often sufficient to prevent a bougie being passed more than a few inches, even in a healthy rectum. But the statement of the patient tends to mislead him also; for she describes herself as going to the water-closet, and yet being unable to eject the contents of the bowels. I will not say that it is so in all cases, but I am satisfied that, in some instances, if you cross-examine the patient, you will find reason to believe that the hysterical constipation of the bowels is of the same nature with the hysterical retention of urine. The effort of volition is not exercised except when the accumulation of *fæces* has become excessive. Hysterical

difficulty of deglutition, which is sometimes mistaken for stricture of the œsophagus, is probably an affection of the same kind; there being no actual spasm, but a defective action of the voluntary muscles, by means of which deglutition is performed.

Symptoms resembling those of tetanus occasionally occur in patients who are under the influence of hysteria; sometimes assuming the form of trismus, at other times that of *opisthotonos*. A case of *locked jaw*, cured by the injection of oil of turpentine into the rectum, and published by Dr. Phillips (then residing at Andover), in the sixth volume of the *Medico-Chirurgical Transactions*, is manifestly one of this description.

In a great number of instances, local hysterical symptoms appear to be connected with some accidental injury—generally a very slight one; and they are then especially liable to be misunderstood, and mistaken for something very different from what they really are.

For example: a woman is bled in the arm. She complains, perhaps, of severe pain at the time; but this subsides, and the wound heals, as under ordinary circumstances. Then she complains of pain again, extending down the forearm to the hand, up the arm to the axilla and shoulder, and even to the side of the neck, and sometimes down the side of the chest also: the extent and degree of pain varying in different cases. You examine the cicatrix, but can discover nothing unusual in it; but the patient flinches when it is touched. She very commonly complains of the surgeon, saying that she was badly bled, or bled with a blunt lancet, or a foul lancet, or that a nerve was pricked which ought not to have been touched; while the real origin of her symptoms may be traced to the peculiar state of her own nervous system. If you investigate the case further, you will always find that she has been liable to various nervous symptoms previous to those which are attributed to her being bled; and when these last disappear, nervous symptoms of some other kind show themselves.

In another case, the patient has received a blow on the head. In order to avert the consequences which such an injury may be expected to produce, she is bled repeatedly, takes aperient medicines, and is kept on a low diet. When her physical powers are thus reduced, she complains of pain in the head even more than she did in the first instance: but the pain is of a different character, and is usually attended with other symptoms, such as do not belong to inflammation. Thus she has a sense of dizziness, or feeling as if water was trickling over her head. Then the countenance is

blanched, the skin is cool, and the pulse is probably small and quick, and weak. If, under these circumstances, the surgeon, mistaking the nature of the case, continues to abstract blood, and to keep the patient on a low diet, all these symptoms become aggravated; other symptoms of a more decidedly hysterical character show themselves, and no improvement takes place until a more judicious treatment is adopted. In another case, which is of no unfrequent occurrence, a young woman pricks her finger, or perhaps the finger is merely pinched. Soon afterwards, she complains of pain extending from the finger upwards, along the hand and fore arm. This probably is followed by a convulsive action of the muscles of the arm, or by a continued contraction of the flexor muscles on the anterior part of the arm, so that the forearm is kept permanently bent; at least while the patient is awake, for the spasm is generally relaxed during sleep.

But the symptoms which, in hysterical patients, are attributed to a local injury, often proceed much further than what I have hitherto described. For example:—

A young lady, eleven or twelve years of age, pricked the fore-finger of her left hand with the point of a pair of scissors. This was immediately followed by pain in the course of the median nerve, and on the following day the fore-arm was fixed by muscular contraction, at a right angle with the arm. After a few days, all the muscles of the hand and fore arm were affected with violent spasms, producing strange convulsive movements of the hand and fore-arm. These were attended with sickness and vomiting, so that for two days, whatever was received into the stomach was immediately rejected from it. By degrees the other limbs became affected in the same manner, and it was impossible for the patient to walk, or even to stand. Sometimes the diaphragm was affected so as almost to threaten suffocation. At other times the jaw was closed by a contraction of the masseter muscle, or she lay in a state of *opisthotonos*. Occasionally there was a violent pain in the head, which was described as having the same character as that of the finger which had been pricked; and these symptoms continued (sometimes one order of them, sometimes another, being predominant) until recovery took place under the circumstances which I shall have occasion to notice hereafter.

With a view to the further illustration of this part of the subject, I shall mention another case. A female about 30 years of age was admitted into St George's Hospital, on account of a simple fracture of both bones of the fore-arm. There was

difficulty of deglutition, which is sometimes mistaken for stricture of the œsophagus, is probably an affection of the same kind; there being no actual spasm, but a defective action of the voluntary muscles, by means of which deglutition is performed.

Symptoms resembling those of tetanus occasionally occur in patients who are under the influence of hysteria; sometimes assuming the form of trismus, at other times that of *opisthotonos*. A case of *locked jaw*, cured by the injection of oil of turpentine into the rectum, and published by Dr. Phillips (then residing at Andover), in the sixth volume of the *Medico-Chirurgical Transactions*, is manifestly one of this description.

In a great number of instances, local hysterical symptoms appear to be connected with some accidental injury—generally a very slight one; and they are then especially liable to be misunderstood, and mistaken for something very different from what they really are.

For example: a woman is bled in the arm. She complains, perhaps, of severe pain at the time; but this subsides, and the wound heals, as under ordinary circumstances. Then she complains of pain again, extending down the forearm to the hand, up the arm to the axilla and shoulder, and even to the side of the neck, and sometimes down the side of the chest also: the extent and degree of pain varying in different cases. You examine the cicatrix, but can discover nothing unusual in it; but the patient flinches when it is touched. She very commonly complains of the surgeon, saying that she was badly bled, or bled with a blunt lancet, or a foul lancet, or that a nerve was pricked which ought not to have been touched; while the real origin of her symptoms may be traced to the peculiar state of her own nervous system. If you investigate the case further, you will always find that she has been liable to various nervous symptoms previous to those which are attributed to her being bled; and when these last disappear, nervous symptoms of some other kind show themselves.

In another case, the patient has received a blow on the head. In order to avert the consequences which such an injury may be expected to produce, she is bled repeatedly, takes aperient medicines, and is kept on a low diet. When her physical powers are thus reduced, she complains of pain in the head even more than she did in the first instance: but the pain is of a different character, and is usually attended with other symptoms, such as do not belong to inflammation. Thus she has a sense of dizziness, or feeling as if water was trickling over her head. Then the countenance is

blanched, the skin is cool, and the pulse is probably small and quick, and weak. If, under these circumstances, the surgeon, mistaking the nature of the case, continues to abstract blood, and to keep the patient on a low diet, all these symptoms become aggravated; other symptoms of a more decidedly hysterical character show themselves, and no improvement takes place until a more judicious treatment is adopted. In another case, which is of no unfrequent occurrence, a young woman pricks her finger, or perhaps the finger is merely pinched. Soon afterwards, she complains of pain extending from the finger upwards, along the hand and fore arm. This probably is followed by a convulsive action of the muscles of the arm, or by a continued contraction of the flexor muscles on the anterior part of the arm, so that the forearm is kept permanently bent; at least while the patient is awake, for the spasm is generally relaxed during sleep.

But the symptoms which, in hysterical patients, are attributed to a local injury, often proceed much further than what I have hitherto described. For example:—

A young lady, eleven or twelve years of age, pricked the fore-finger of her left hand with the point of a pair of scissors. This was immediately followed by pain in the course of the median nerve, and on the following day the fore-arm was fixed by muscular contraction, at a right angle with the arm. After a few days, all the muscles of the hand and fore arm were affected with violent spasms, producing strange convulsive movements of the hand and fore-arm. These were attended with sickness and vomiting, so that for two days, whatever was received into the stomach was immediately rejected from it. By degrees the other limbs became affected in the same manner, and it was impossible for the patient to walk, or even to stand. Sometimes the diaphragm was affected so as almost to threaten suffocation. At other times the jaw was closed by a contraction of the masseter muscle, or she lay in a state of *opisthotonos*. Occasionally there was a violent pain in the head, which was described as having the same character as that of the finger which had been pricked; and these symptoms continued (sometimes one order of them, sometimes another, being predominant) until recovery took place under the circumstances which I shall have occasion to notice hereafter.

With a view to the further illustration of this part of the subject, I shall mention another case. A female about 30 years of age was admitted into St George's Hospital, on account of a simple fracture of both bones of the fore-arm. There was

nothing unusual in the fracture, but she complained of an extreme degree of pain in the injured part. By degrees the pain extended up the arm to the axilla; then to the same side of the neck and head. The smallest motion of the limb, even the lifting the fore-arm off the pillow on which it lay, occasioned violent pain, and convulsive agitation of the limb, which were soon followed by what might be termed a state of hysterical syncope, in which the patient lay apparently insensible to external impressions for several minutes. The fracture united as under ordinary circumstances; but the nervous symptoms continued for many weeks, then subsiding gradually. It is worthy of notice (and this circumstance confirms the opinion, that symptoms of this kind belong more to the constitution than to the actual injury), that about two years before the occurrence of this last accident, this individual had met with a slight injury of the ankle, for which she was attended by Mr. Fuller, of Piccadilly; and that a train of nervous symptoms at that time supervened, nearly similar to those with which she was afterwards affected in the hospital. It is also worthy of notice, that on both occasions she had occasionally a spitting of blood, probably furnished by the mucous membrane of the pharynx or trachea, as there was no reason either at the time, or afterwards, to suspect the existence of disease in the lungs.

I have seen several cases of a singular affection of the hand and wrist, which manifestly belongs to the class of cases of which we are now treating. It occurs in females who have a disposition to hysteria, especially in those who have suffered from mental anxiety and over-exertion, and is usually, but not constantly, referred to a sprain, or some other slight accident. The patient complains of pain in the back of the hand and wrist, trifling at first, but gradually becoming more severe. In many instances, after some time has elapsed, there is a diffused swelling of the soft parts, extending a short distance up the lower extremity of the fore-arm; and downwards as low as the fingers. This swelling is not attended with redness of the skin; and having lasted for a few weeks, it subsides, while the pain remains, constant in its character, aggravated by every motion of the limb, and always more severe in proportion as the patient's attention is in a greater degree directed to it. To prevent the motion, which she so much dreads, the patient keeps her hand in one position, and the consequence is that the joints become comparatively stiff, the hand at the same time having a very cha-

racteristic appearance, the skin being smooth and shining, and appearing to adhere more closely than is usual to the parts beneath. This state of things may continue for three months, for six months, or even for one or two years; the symptoms then gradually subsiding, without leading to any further ill consequences. The result, however, is not always so fortunate. I attended a lady who laboured under the symptoms which I have just described, with the late Dr. Luke. She left London on a visit to the continent, without any amendment having taken place. I saw her again after the lapse of four or five years: the muscles of the fore-arm were at this time wasted and paralytic; the whole hand was shrivelled and useless; the fingers permanently contracted towards the palm of the hand; the nails thin and scabrous.

I shall conclude the present lecture by a brief notice of some cases, which will serve to illustrate further the variety of singular local symptoms which may arise as a consequence of hysteria, and which may fall under your observation as practitioners in surgery.

I was consulted concerning a young lady, 18 years of age, under the following circumstances. She was liable to fits of incessant sneezing, attended with a most abundant flow of watery fluid from the nostrils. This sometimes alternated with a nervous cough; while at other times she suffered from that sensation in the throat which is usually described under the name of *globus hystericus*. Not unfrequently she was affected with ordinary paroxysms of hysteria. She had a feeble circulation, and cold hands and feet, and her menstruation was irregular and deficient; in other respects she was in good health. There was no evident disease in the nostrils.

A married lady, 37 years of age, was affected with similar fits of sneezing, attended also with a copious watery discharge from the nostrils. These symptoms attacked her once in a week, and in each of these attacks she sneezed not less than one hundred times; the watery fluid dropping from the nostrils so as to wet a pocket-handkerchief completely through. About the same time she began to experience a disagreeable sensation in the face and palate, not amounting to pain, but which she described to be such as might be produced by a worm creeping in her flesh. These latter symptoms gradually became more distressing, while the fits of sneezing became less frequent. At the time of my being consulted, three years after the

commencement of the disease, the fits of sneezing did not occur oftener than once in a month, but she complained of an aching pain, with a sense of pulsation, in the roof of the mouth, the teeth, and tongue, occurring chiefly during the night, and being then very severe. There were no perceptible marks either of inflammation, or of other disease, in the parts to which the pain was referred.

An unmarried lady, 32 years of age, consulted me on account of her being liable to some very distressing paroxysms, in which she experienced a difficulty of respiration, attended with a sense of constriction of the chest, and great general excitement and agitation. These paroxysms often continued for ten or fifteen minutes, recurring at irregular intervals; sometimes without any evident cause; while at other times they might be traced to some sudden emotion of the mind. So far the case did not differ from many other cases of hysteria; but the peculiarity of it, and the circumstance which led to my being consulted, was as follows:—There was a particular spot, near the ensiform cartilage, which she believed to be in some way or another connected with her complaint. Nothing could be discovered in this part different from what is usual, by the most strict examination; but the pressure of the finger on it never failed to induce one of the paroxysms which I have just described. When these paroxysms were most severe, they were always attended with an abundant flow of limpid urine. These symptoms had existed in a greater or less degree for ten or twelve years, and had supervened on a state of exhaustion occasioned by an attack of typhus fever.

A young married lady, who was liable to ordinary attacks of hysteria, complained of a tender spot on the anterior part of the abdomen, a little below the ensiform cartilage. The slightest pressure of the finger on it caused excessive pain, and was followed by violent agitation of the whole person, bearing a more near resemblance to the convulsive motions of *chorea* than to any thing else, and continuing for several minutes.

AN ILLYRIAN DWARF.

THERE is at present in Paris a dwarf aged 22 years, and not three feet high. His name is Matthias Gulia. He was born in Illyria, not far from Trieste, of parents of good size and shape. Gulia exhibited nothing anomalous in his formation till he was five years of age, when he

ceased to grow. He is distinguished from individuals of his own height by his cultivated mind, and his excellent proportions. He speaks five languages—the Croatian, Illyrian, German, French, and Italian. He is, moreover, accomplished: plays the violin very well, is fond of being on horseback, and is a good sportsman.—*Journal Hebdomadaire*.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

MR. EARLE, THE PRESIDENT OF THE SOCIETY, IN THE CHAIR.

THE first meeting of the society this season was held on the 8th of November, at half-past eight o'clock P.M., in the Society's house, 53, Berners-street, Oxford-street.

A considerable number of the Fellows, as well as many visitors, attended, and numerous presents of books were announced to the meeting.

The first part of a paper was read, entitled,

“*Necrosis; being an Experimental Inquiry into the Agency ascribed to the Absorbents in the removal of the Sequestrum*,” by GEORGE GULLIVER, Esq., Assistant-Surgeon to the Forces.

It was communicated by Sir James Macgrigor, Bart.

The object of this paper was to determine what becomes of the dead bone in necrosis, and by what means it is replaced. The first part of the paper only was communicated to the society, and this was confined to the question—“whether dead bone admits of removal by absorption;”—the consideration of the other means by which it may be discharged was reserved for a future communication.

The opinions of the author, derived from preparations contained in the museums of anatomy and pathology, from cases, and from experiments, went to show that the absorbents have no power in removing dead bone; and that the facts which have been brought forward in support of a contrary opinion may be otherwise accounted for. These facts were shortly enumerated in the paper as—1st, the gradual disappearance of the sequestrum in many cases of alleged necrosis; 2d, the irregular and eroded state of the dead portion; 3d, the contact of granulations with the indentations on its surface; 4th, the absorption of the fang of a transplanted tooth; and, 5th,

portions of dead bone have diminished in weight after having been kept in contact with the granulations of an

author, in taking a review of these asserts, with respect to the alleged disappearance of the sequestrum, that cases have been described as necrosis in reality have been thickened the result of long-continued inflammation, in some of which small fragments of dead bone have been detached from their interior; that the deposition of bone around the old is not an absolute proof of the death of the latter; that he has observed several cases in which pieces of dead bone have remained for months in contact with living bone unaltered in form, size, and weight. The worm-eaten appearance on the surface of many sequestra, he refers to the absorption and separation of the bone, and attributes to the effect of the ulcerous process while the part retained its vitality, than to the action of the abscess after its death.

On the aspect and situation of the granulations with respect to the sequestrum he believes to depend in some cases upon the extension of the ossific process into the soft parts, and in others upon the work of excretion. The disappearance of the fang of a transplanted tooth seems, in the author's opinion, to indicate that it preserved vitality, and that accordingly it became subject to the laws of the living body of which it formed a part.

Gulliver relates, in his communicative cases and no less than sixteen experiments to show that dead bone, when in contact with ulcers—when buried in the soft parts of the body—or when placed either on the surface or in the interior of living bone—undergoes no change of weight, or appearance. In conclusion, the author repeats his belief that absorbents are not the means by which the portion of dead bone, or the sequestrum of necrosis, is removed.

Signature of the External Iliac Artery.

The next communication read to the Society was the sequel of a case, related at p. 95, in the 10th volume of the Med. Chir. Trans., in which the external iliac artery was tied by George Norman, of Bath. The subject of this history lived twenty years after the operation, and continued free from aneurismal swelling up to the period of his death. The wax was injected from the lower part of the aorta, and the wax ran freely even into the minute vessels of the foot. It was found on dissection that the external iliac artery was obliterated from its origin to a

little above the point where the epigastric and circumflexa ilii arteries are given off. A mass of fibro-cellular substance occupied the situation of the common origin of the profunda and external circumflex arteries, which, though obliterated, could be distinctly traced to the femoral, which was pervious in its whole extent. The collateral circulation had obviously been carried on by the ramifications of the internal iliac, as follows:—

1. The ilio-lumbar anastomosing with the circumflexa ilii and the external circumflex.
2. The obturator with the epigastric and internal circumflex.
3. The gluteal with the external circumflex.
4. The ischiatic with the perforating branches of the profunda.
5. The internal pudendal with branches of the internal circumflex.

All these arteries were larger than natural.

At the close of the meeting, the President announced that in future no papers could be published in the volumes of the Transactions, unless they had been previously read before a meeting of the society.

At the next meeting, a paper will be read on "Atrophy of Bone," by Mr. B. Curling.

PROCEEDINGS IN CAMBERWELL.

POOR LAW MEDICAL CLUB.

To the Editor of the Medical Gazette.

"And shall we own such judgment? no; as soon
Seek roses in December, ice in June,
Hope constancy in wind, or corn in chaff,
Believe a woman, or an epitaph,
Or any other thing that's false, before
You trust in critics, who themselves are sore."

SIR,

PASSING over any attempt to convince your constant correspondent, Mr. Crisp, that Messrs. Flower and Young are neither of them Dutchmen, I shall make a few observations on the conduct of those gentlemen who came, some like the wise men from the east, others from the west, the north, and the south, to bestow upon the practitioners of Camberwell terms of the most "enlightening character;" and so delighted were they with the success of their mission, that I believe it has since been celebrated "where sit, involved and lost in curling clouds of Indian fume, all loud alike, all learned, and all wise," some of those persons whose sweet voices made the room at Camberwell echo with the melodious notes of black sheep, &c. &c.

Being present at this first meeting, and witnessing what I am not singular in calling "din and confusion," and which Mr. Crisp, although not present, did not on that account refrain from giving his account of it, I do not see why I should not give an account of the second, seeing all those with whom I have conversed upon the subject, holding different opinions on the formation of a Medical Club, and who were present upon the occasion, were unanimous in describing it as the most disgraceful scene they had ever witnessed. One gentleman told me that if I complained of such terms as "black sheep, not upholding the honour and dignity of the profession," it was positive politeness compared with some of the terms made use of at the last most triumphant meeting. Another, who was not favourable to the Club, declared he was so disgusted with the proceedings as to leave the room with a full determination never to attend another medical meeting. A third gentleman stated that "thieves, traitors, robbers," and other such like terms, were used; and at length, fearing that the parties who talked of shedding the last drop of blood in the cause would suit the action to the word, thought it better not to wait the "tug of war," but act on Falstaff's maxim—deeming discretion the better part of valour: and he also left. I could give their names, but as they said they were heartily "sick of physic," they begged to be excused. Had there been nothing more than the parties on each side stating their opinions on the question, without imputing motives and offering personal insults by wholesale, I should never have put my pen to paper on this subject; and it is to such conduct as this I apply the term "gross abuse:" I think it quite unnecessary to waste words about posting the names, after seeing them published in the following week's GAZETTE. I am aware that verbal statements are not considered so authentic as written; I therefore quote the imputation of "concerting measures to take the bread out of the mouths of the poorer class of surgeons," as applied to "Forbes, Bean, Brown, and Flower:" and as defiance seems to be the order of the day, I defy either Mr. Crisp, or Mr. Bowen, or those other gentlemen who have not yet thrown off the mask—who have not yet come out from their hiding places—and who have taken far more pains than Mr. Crisp to ascertain whether Messrs. Flower and Young pay a rate for a Camberwell gas-light, or are one foot removed out of Camberwell parish! and I doubt not but as the masks fall from their faces, and they come out from the Holland Street Dutchman, we shall recognize faces darker and longer than any that yet figure on the

scene; and as we gaze in mute astonishment upon the mottley group, we may well exclaim, "Pity that all these should be defied to prove the charge of "concerting"! Yes; but methinks I already hear some one assert,—It is easy for us to get through all our difficulties; try first the scheme that has silenced all who have yet ventured to oppose us: you have only to put on the "assertion and misstatement extinguisher; and in case that fail, try the Dutch mode of recapitulating the arguments"! I put it to any candid mind to say, whether Mr. Crisp, in what he calls the recapitulation of my arguments, has not "mapped them out in such a way as to suit his own purpose." Mr. C. states that the very basis of the system is unstable and rotten; for it is founded in an untruth—that the members are told they will become independent, when, in fact, they are in a state of dependence; and that the great evil of the scheme is—that it holds up a bait for the upright man to leave the path of honesty, &c.; and yet with wonderful sagacity admits—that the plan may be practicable in a coal mine! I think it requires but little argument to show that, according to this doctrine of independence, we are all living in a state of dependence, from the king down to the lowest subject.

I stated, as he will see, if he will take the trouble to read my letter over, that there were a numerous class of professional men who considered it no degradation—no dishonour—to the professional character, to lend their assistance in raising the moral condition of the poor, by cherishing that feeling of independence, &c. This is widely different from stating this system will raise the moral condition of the poor, and make them *independent* in Mr. Crisp's sense of the word. I again assert, that we cherish a spirit of independence when we place the poor in such a position as enables them (by our accepting a small sum suited to their circumstances) to obtain our assistance without being deterred by a fear of incurring to them embarrassing pecuniary liabilities; and small, indeed, must be his experience of the feeling of which I speak, who supposes I mean by independence "riding in an elegant chariot, receiving his guineas," &c. I envy not the feelings of any man who can come to this question wresting words from their legitimate meaning, or arraying himself in the flimsy mantle of the wrangling logician. The independence, sir, of which I speak is that of the spirit which those who harbour in their own breasts would gladly see diffused around them: it is a spirit which, retaining a rational desire to perform the relative duties of life, would yet scorn to receive that as a de-

graded pauper which is placed within his reach as a positive right. Yes; I would cherish this feeling even at the risk of being occasionally overreached by the cunning and dishonest; and as to not being able to compel the latter class to pay towards the Club, I am not sure that the club is not better without than with them; at all events, if it be an evil, it is one that if left to itself will work its own cure: it will at any rate prevent the dishonest man wearing the mask of the honest; and if without his mask he cheats the profession, it will be their own faults: and as to the objection of the higher grades adopting it, "I said under judicious limitations," by which I meant to be understood, the exclusion of abuses. It is not a fair mode of argument to bring against the usefulness of this or any other measure, the abuses to which it may be liable in common with every thing else that is good and beneficial to mankind: if such a mode of argument be permitted, will any of the noble institutions which have for ages been the praise and admiration of the wisest and the best of men, bear the test of this method of attack? Independent, indeed, as they are called, they are still, according to the doctrine of Mr. Crisp, based on a rotten and unstable system, founded on the "untruth" that while they are independent, they are yet in a state of dependence. Equally absurd is it to suppose that a system founded for the express purpose of preventing the poor man sinking into absolute pauperism, should be held up as a bait for the upright man to leave the path of honesty and "independence," to walk in that of pauperism. I need not argue this point, as there are none independent, according to Mr. Crisp's doctrine, and therefore the path is of no use; so that the bait is quite superfluous, as no wise man thinks of fishing in a pond where he knows there are no fish. I did not state that the medical practitioners in his neighbourhood were in the habit of sending in ruinous bills to the poor; so that the tone of defiance, like the bait, is quite superfluous: I did not offer to bring forward any invidious distinctions of those ruined by paying a long bill; and when I stated that the advantages of medical clubs offered the poor the option of selecting their own medical attendant, I was not such a Dutchman as to think I spoke of a shadow: I took for granted their formation.

And now, sir, a few words on the degradation implied in the swinish simile of physicking a pig, which has no legitimate bearing on the subject; the contested principle not applying to individual sixpences or shillings, but mainly to the aggregate; the many constantly making up a purse to defray the exigencies of the

few; probably by such means insuring an amount equal to that which many practitioners are now receiving for attendance on the various metropolitan institutions. I am accused of placing the highest grounds in the foreground, and suspecting the grand secret of non-remuneration would be found concealed under the mask of the zeal for the honour and dignity of the profession. I placed before them in the prominent part of the picture the gist of the question on their side of the argument, and then, as if touched by the magician's wand, the mask suddenly fell off, and presented in large and flaming characters this motto:—"A less sum than the village farrier would expect for physicking his pig." Not having instituted any comparison between young gentlemen (who either have or have not attended lectures) with the parish midwife, I feel it unnecessary to enter on that subject.

"O wad some power the giftie gie us
To see oursel's as others see us!
It wad frae monie a blunder free us
An' foolish notion."

That each individual has a right to form and enjoy his own opinion I readily admit; but to impute unworthy motives to others—to descend to low and vulgar terms of abuse—or to palm individual opinions on the public as the sense of the profession, this I utterly deny: it was disgust with such conduct that drew forth my first letter. Attached as I feel to the profession of my choice, and jealous of all its properly defined rights and immunities, and desirous of cultivating a good understanding with all my professional brethren, I should have reviewed even more narrowly than I did the steps by which I arrived at my determination, had the subject been fully, fairly, and rationally discussed. It, however, affords me satisfaction to find so many of my professional neighbours have come to the same conclusion as myself. I presume not to say that I am right in the estimate I have formed of the worth of this system; but inasmuch as the advantages of theoretical data are far outweighed by the possession of practical realities, and garnered experience availeth more for useful purposes than the thick darkness of gainless uncertainty, I trust, with so many in its favour, it will not be condemned, or rather I should say abandoned, without being put upon its trial.

Were this, indeed, a question involving any "professional rights,"—something beyond the mere breaking a fly upon the wheel, or impaling a beetle,—I trust I feel I should be found in the vanguard of the onslaught; but to wage a puny warfare with "emaciated want,"—to gnarl over a fleshless skeleton,—or to make keen a

weapon against a keener misery, is to achieve such honour as my humble ambition descrieth not even from afar, and for which I have neither aim nor hope to imitate; and although this system comes recommended by the Poor Law subordinates, why are we to be frightened from our propriety to espy the mountain in the mole-hill, or with the distempered imagination of the monomaniac, to conjure up more devils than vast hell can hold, even in the fleshy form of Poor-Law Commissioners?

— "Tigris agit rabidâ cum tigride pacem
Perpetuam, sævis inter se convenit ursis."

But whilst possessed of the *mens sana*, and enjoying the blessing of sober consciousness, I hope to see things as they really are, and not through the medium of an affrighted or distorted imagination. I have to crave your indulgence for so soon after taking my leave, again intruding on the columns of your journal; but not liking to be silenced, either by the misstatement extingisher, or the Dutch mode of recapitulation, I am induced to appear again before you to offer thus much in explanation.

"What right, what true, what fit, we justly call,
Let this be all my care—for this is all."

J. S. FLOWER.

Camberwell Green,
Nov. 1, 1836.

CAMBERWELL PROJECTED CLUB.

MR. HULBERT'S REJOINDER.

To the Editor of the Medical Gazette.

SIR,

WHEN I last addressed you, I had not intended continuing a controversy relative to the late occurrences at the Camberwell meeting, at which the *honour of the medical profession was so opportunely and spiritedly redeemed*; but the facts mentioned in my first letter having given rise to many fallacies, and to none more obvious than that of their being represented as *mis-statements*, with the incorrect account given by Mr. Crisp in the GAZETTE of October 22d, in justification of those personalities to which he candidly acknowledges he descended, has inclined me to a different course.

The correctness of the account I gave of the conduct displayed towards me at that meeting being known to all who were present, I should have considered the attempt to represent it as a *falsehood* as too contemptible to notice, had it not been for the extensive circulation of your journal amongst the most

respectable classes of the profession, with many of whom, in different parts of the country, as well as in the metropolis, I have the honour of being personally acquainted.

To several who were at the Camberwell meeting it must have appeared exceedingly strange to have witnessed the reception given me by Mr. Crisp and a few others who are *non-residents* in Camberwell; and stranger still to have read the veritable account transmitted to the Lancet, that the "*honour of the profession had been so opportunely and spiritedly redeemed*" on that occasion.

If it is a "*redemption of honour*" to have recourse to "*invectives, personalities, and misrepresentations*," we are certainly arrived at a new era of the profession, and must henceforward consider those principles advocated by Percival, Gregory, and other writers on *medical ethics*, as the vague theories of bewildered imaginations, glittering, like *ignes fatui*, with delusive light, to lead their followers into the gulphs of error and confusion, and not as the result of experience, reason, and strict propriety of moral conduct.

In his letter of the 22d ult., Mr. Crisp has commenced in so emboldened a strain, that, with the determination of carrying every thing before him, "*he trusts you will give insertion to all his statements, as he is prepared to prove their correctness*." Had all his statements been correct, they would unquestionably reflect a vast deal of professional honour upon him in giving them publicity. But with the view of undeceiving those who may have read his statements, more than with the intention of justifying myself, I now address you, in order to give an explanation of the *very correct accounts* which he has brought forward.

In the first place, Mr. Crisp observes, that at the Camberwell meeting I had made the following statement:—"I am sure I do not wish to act in opposition to my professional brethren." This is partly, but not wholly, correct; for when speaking of my having advocated the cause of Self supporting Dispensaries, I very well recollect saying, that "*had I ever considered they would have a tendency to injure or degrade the medical profession, I would not have taken the steps I had done, as I had no wish to act in opposition to the welfare or respectability of the profession; but that I was firmly convinced, as regarded such institutions, that they would not be prejudicial to the real interests of my professional brethren, or to the welfare of the public*." How far the "*whole tenor of my proceedings has not been actuated by this feeling*," it remains for those of my professional brethren to

decide who are better acquainted with me than the author of such a statement, and who can look upon my conduct with an unprejudiced eye and unperverted imagination.

The circumstance of my coming into this neighbourhood a stranger, ought to have entitled me to the courtesy generally shown to strangers; how far this was shown to me at the meetings at Camberwell, Newington, and Southwark, let those who were present at those meetings determine. In the circular to which an allusion has been made, it was mentioned, that "for several years past a considerable portion of my time had been devoted to the medical attendance of the poor; and that having witnessed the good effects of Self-supporting Dispensaries, I had invited my esteemed friend, Mr. Smith, the projector of those institutions, to explain their principles and advantages to the clerical and medical professions, and any others who feel an interest in the welfare of the poor." This statement I made chiefly on account of my being, comparatively speaking, a stranger. Above 400 copies were printed, and a man accustomed to distribute circulars employed, on the 5th of August last, to deliver them according to their directions. Unacquainted with the names and residences of my professional brethren in this neighbourhood, including Newington, Walworth, Camberwell, &c. &c., I requested a few friends to assist me, and by one medical gentleman I was favoured with upwards of fifty names, exclusive of those given me by others, to each of whom a letter was addressed. To gentlemen of the clerical profession very few were sent; and I am not aware of there having been *one* at the first, and I believe not more than *three* or *four* at either of the subsequent meetings. It has been stated by Mr. C. that a very small number of these circulars reached the medical profession; and that "my excuse for the omission was, that my boy was unable to find the residences of the medical men, and therefore returned the circulars." This account is incorrect, as I mentioned that the man whom I had employed, and paid for his trouble, had only performed part of his duty, and that I had endeavoured to remedy this deficiency as much as was in my power and the shortness of the intervening time would allow. A sufficient number of the circulars were, however, distributed, to ensure the attendance of at least three to one of any other class of persons who were invited.

In the next place, Mr. Crisp asserts that at the adjourned meeting (September 7th), he "found me sitting with men who characterized the members of our profession as gross mercenary conspirators," &c. This is so glaringly incorrect, and such a

perversion of the truth, as to require a more particular explanation. So far from his finding me siding with the gentlemen alluded to, when I entered the room himself and others were assembled, the chair had been taken for several minutes, and the business of the evening had commenced; and during the remainder of its continuance I was in a different part of the room, for the convenience of being near the chairman, and had not ever seen either of those gentlemen before. The hostility displayed to a measure acknowledged, by many who opposed themselves to it, to have an excellent tendency in respect to the industrious though poorer classes of society, and that their opposition arose from the apprehension of its interfering with their professional interests, and that they were determined if possible to crush it, together with the hissings and clamour displayed against the promoters of such a measure, excited the indignation of some who wished to inquire into the merits of the cause, and led to a warmth of expression which they doubtless (at the time) considered themselves justified in employing. The sneering and contemptuous manner in which the allusion to the parable of the good Samaritan, and the precepts contained in the sacred volume, were received, also excited a feeling of indignation, that men, who in the exercise of their profession, especially among the lower orders, are witnesses of much human suffering and misery, should consider the doctrines of Him, "who went about doing good, and healing all manner of diseases," as deserving of their contempt and ridicule. I will not enlarge upon this point, which, however it may raise another sneer at my expense, I do not hesitate to declare, exerts considerable influence on my mind, being aware that theological polemics should as much as possible be refrained from on occasions like the present. I will therefore pass on to the next statement of Mr. Crisp, wherein he asserts that, in writing to the Editor of the Surrey Standard, I had called his account impartial, "when I knew that the reporter only gave the arguments of those who were favourable to the plan." This also partakes of incorrectness, and facts can here speak for themselves. The report published in the Surrey Standard of Sept. 10th was the least incorrect of any which has appeared relative to the Newington meeting of Sept. 7; notwithstanding the assertion of a correspondent signing himself "Chirurgus," in the following number of the same journal, that "a more partial, one-sided statement was never penned." Upon referring to it I see no cause for altering my opinion. Let the report be compared with that in the Lancet (so celebrated for *correctness* and *impartiality*) and then let

any unprejudiced person be asked which account presents the character of one-sidedness, and which the contrary.

I am, sir,
Your obedient servant,
J. F. HULBERT.
6, Trinity Square, Southwark,
November 2, 1836.

[Want of space obliges us to omit that part of our correspondent's letter which relates to Mr. Crisp's remarks on the communication from Mr. Hawes, M.P., which was read at a subsequent meeting.—E. G.]

PARISH UNIONS.

QUERY FOR AN OLD NAVY SURGEON.

To the Editor of the Medical Gazette.

SIR,
MAY I, through the medium of your valuable periodical, ask your correspondent, the Old Navy Surgeon, if he wishes your readers to understand 11,800 to be the pauper population of those sixteen parishes comprising the union, one of which, Grove, in Bucks, has twenty-one inhabitants. I rather suspect he has been calculating the gross population; if so, all his computations and comparisons are wrong. He feelingly describes the discomforts of the union officers, forgetful all country practitioners are exposed to the same. I do not intend to discuss point by point, but I consider the whole account to be exaggerated; and being a constant reader of your work, I feel regret it should be made the channel of such communications.

If you consider this worthy of a niche in your columns, you will oblige,
Your obedient servant,
E. C. T.

Nov. 9, 1836.

[We have no doubt the "Old Navy Surgeon" will readily explain.—ED. GAZ.]

ANECDOTE OF DUPUYTREN.

THE late M. Dupuytren in his last illness had effusion into the chest consequent on a pleurisy. He was at first disposed to have himself tapped for it; but three of his medical attendants being against, while two were for, paracentesis, he changed his mind, and observed, "I would rather die by the hand of God than of man!"—*M. Husson in the Acad. de Méd.*

HINT TO PHRENOLOGISTS.

A DR. GAUBERT, who has been holding forth at the Phrenological Society in Paris, on the skull of a lady who died lately, has got himself into a scrape with

her relations. They have brought an action against him for defaming the family, in the remarks which he made on the character of the deceased; and a newspaper which reported the defamatory trash has been included in the action. The trial was to have taken place on the 9th instant.

APOTHECARIES' HALL

LIST OF GENTLEMEN WHO HAVE RECEIVED
CERTIFICATES.

November 10, 1836.

John Senior Turner, Gleadthorpe Grange, Notts.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE VIII.

Medico-Legal relations of the Reproductive Function—Inability, or Impotence, a ground of Divorce—Legal distinctions respecting the Marriage Contract—Suits of Nullity of Marriage.—IMPOTENCE IN THE MALE: 1. Physical Causes—Inadequate or imperfect Development—Some curious Cases—Castration—Extraordinary Case of Count Sorlisi.—2. Moral Cause—Fascination, or Witchcraft—Fear—Desire—Habits of intemperance—Partial impotence—Errors of the ecclesiastical or canonical authorities—Speculations of theologians.

WE now enter upon a large class of relations, embracing subjects of much interest and importance in Forensic medicine. I allude to those connected with the generative or reproductive function. When I lately treated of Sex, I did so merely with reference to structure, whether normal or abnormal, and without any special regard to the uses of the parts. I shall, however, now have to notice those uses,—and the abuses also.

Questions arising out of the consideration of the sexual functions are usually divided under the several heads of Impotence and Sterility, Violation, Pregnancy, Abortion, and the Births of children.

Legal distinctions.—Certain legal consequences are attached to the imperfect exercise of the sexual functions, and it devolves occasionally on the medical jurist to determine how far the power of ministering to reproduction exists in the indi-

vidual. In respect to marriage, some of the most valid grounds of divorce rest on the proofs of inability; and in charges of violation, abortion, &c., evidence of the fact is almost equivalent to exculpation.

As I shall hereafter treat distinctly of the subjects involved in the latter charges, I shall confine myself on the present occasion principally to the question of inability in reference to marriage.

I must premise, that I intend not at present to consider all the medico-legal circumstances connected with marriage, but only those which have relation to the chief object of the married state, as contemplated by the laws,—the procreation of children. Other considerations which may also form grounds of divorce, may more properly be introduced hereafter.

Marriage, how contemplated by the law.—Marriage, in the eye of the law, the common law of England, is simply a civil contract. The holiness of the wedded state is an attribute which it possesses in the estimation of the ecclesiastical or canon law; and in countries where this law prevails more than it does among us, it will be readily understood that there is ample room for casuistry, and for much medico-legal, as well as juridical interference.

The business of the medical jurist, in this country, is considerably limited, in relation to the question of marriage, in consequence of the plain view taken of the contract by the law of the land: still, however, the difficulties which occasionally occur, and which it is the province of the professional witness to remove, are by no means of a very simple or superficial nature; on the contrary, they require our best and gravest attention.

Conditions of the contract.—The conditions which render a marriage legally valid, are briefly those which constitute the validity of any other contract,—namely, that the contracting parties be willing, that they be able, and that they

shall have complied with certain requisite formalities. Now it is on questions connected with the two first conditions that the medical jurist is sometimes required to lend his assistance. He may have to consider whether the parties, or either of them, be capable of exercising a will or a discretion, in respect to entering on a matrimonial contract: one or other, or both the parties, may be disqualified, for example, by reason of too tender or too advanced an age, or there may be some imbecility or unsoundness of mind, not admitting the exercise of a will. Of such a state of things, I shall enter on the consideration in a future lecture.

On the other hand, as to the condition of being *able*, it will probably be the duty of the medical jurist to examine how far either party is qualified in respect to bodily circumstances. He may have to show whether either party does or does not labour under certain disabilities which would invalidate the contract; under certain corporeal infirmities, in fact, existing at the time the marriage is celebrated.

Non-age.—I have already mentioned the ages recognized for legally forming a marriage-contract at the earliest—fourteen for the male, and twelve for the female. But the ecclesiastical courts look rather to the habit, strength, and constitution of the parties; they only inquire whether they be *habiles ad matrimonium*, and not how many years they may have numbered: and, indeed, the common law will hold even infantile marriages, solemnized with due formality, valid, when the parties, on reaching the ages just stated, do not demur to the contract.

Sexual inability.—The corporeal imperfections are chiefly those constituting impotence, or an inability to have sexual intercourse; and this may belong either to the male or the female. Neither party should be impotent at the time of the marriage; and should it afterwards appear that either was—that, in fact, the marriage was not consummated, and that the inability continued—it is a ground for annulling the marriage in the ecclesiastical courts, although the party so disqualified was ignorant that the defect existed at the time.

Grounds of divorce.—It is to be observed, that there are two kinds of divorce; the one, which may be considered complete, *à vinculo matrimonii*; the other incomplete, *à mensa et thoro*. Now impotence is a principal ground for obtaining the former; and in suits for that object, the party complaining must prove that the incapacity existed at the time of the marriage, and continued to be of a nature incurable: if the impediment was not natural, but supervened after the

marriage, there is no sufficient ground of divorce.

“In a suit of nullity,” says Mr. Chitty, “by reason of the alleged impotency of the husband, a certificate twelve years after the marriage, that the wife still was *virgo intacta*, although *apta viro*, coupled with two several confessions of the husband of his incapacity, and with proof that the woman’s health had suffered, though the husband had not given in his answers, and that he had removed into France, and had refused to undergo surgical examination, was holden sufficient in the ecclesiastical court. On the continent, suits for a divorce on this ground are frequent; but for the honour of English ladies, their delicacy in general deters them from thus publicly complaining; and such suits are comparatively rare, unless there be other strong ground for seeking a dissolution of the contract—as intolerable ill temper, which, although of itself not a sufficient ground for a divorce, may yet constitute an inducement to make the disagreeable disclosure, and proceed for a divorce on the legal ground of the incapacity of the husband.”

Distinction between sterility and impotence.—Impotence, as I have said, may belong to man or woman; and so may sterility,—understanding by this term, an inability to be prolific. Sterility implies, that notwithstanding the existence of an aptitude for sexual intercourse, there is no power of procreation. This species of inability, however, is more commonly imputed to the female than the male; for where no charge of impotence can be established against a man, it is difficult to make out his sterility, though there may be strong presumption that he is *bond fide* unprolific.

The question of sterility in either sex is in great measure inferential, and the fact is generally dependent on internal organization, of which the medico-legal examiner cannot in general have sufficient cognizance in the living body. For this reason, and because in suits of divorce it is the question of impotence which is principally entertained, we may, perhaps, more usefully direct our attention to this infirmity than the other, although both are so closely connected, that it were not possible, even if desirable, to wholly separate the consideration of sterility from that of impotence.

We may divide the subject as it relates to males and females: and first let us inquire what are the causes and signs of

IMPOTENCE IN THE MALE.

Inability to have sexual intercourse may in man arise either from physical or moral causes.

1. *Physical Causes.*

sufficient development.—The age of a man may be such as naturally to exclude the idea of potency. Previous to puberty, no individual must be presumed, and is held by the criminal law, to be incapable of the generative act: the seminal secretion has not yet begun, and the stimulus derived from that source is consequently absent. On the other hand, old age has extended its withering influence on the sexual parts, and the man who in youth may cease to be so any longer. The limits of either period cannot be fixed. Puberty is in many retarded, in many accelerated, owing to various causes: the climate, habits, and education, and constitutional peculiarities, have material influence; and we have on record many examples of precocious puberty, and not a few of late development.

In respect to the aged, it is still more difficult to say when, even on an average, the powers of procreation cease. Aristotle, has fixed on the seventieth year; but there are instances might be adduced to show that the generative power has often lasted to a period much more advanced. We have says he has known examples of men who were still prolific at ninety.

The celebrated Banbury Peerage case, has been urged among other arguments in support of the claimant of the title, that the man under whom he claimed could not have been the son of Lord Banbury, that nobleman was 80 years old when the child was born. The remarks of Lord Erskine on this point are worth repeating:—"But what evidence is there of Lord Banbury having been impotent?"

There is no statute of limitations on the powers and faculties of man. Instances of great longevity might be cited still more extraordinary. Sir Stephen Fox was at the age of 77, and had four children; the first child was born when he was 78, the second and third in the following year, and the fourth was born when the father was 81. He was a father when even his son was a more advanced age than Lord Banbury.

Samuel Romilly, in his observations on the same head, thus expresses himself:—"Objection to the age of Lord Banbury at once be dismissed. The law does not admit of no age at which a man may not become a father; and many authorities may be cited to show that the rule is founded on reason. Dr. Black, of Edinburgh, whose name must be familiar to all admirers of science, says on this subject:—"Magna autem de his differentiis; decantantur enim eximium in castris Veneris strenue

merentium, postquam centum annos compleverant; neque sane dubium, aut adeo rarum octogenarium patrem fieri.' Haller likewise pronounces a man of 90 to be capable of procreating. Parr became a father in his 140th year. In short, the liberality of the law on this subject is excessive, for there is no age, from seven upwards, at which a man is denied the privilege of having children." I take both these extracts from Mr. Le Marchant's book on the Gardner Peerage.

(b.) *Imperfect structure.*—A more obvious cause of impotence is found in an imperfect structure of the genital organs. Either owing to congenital malformation, or some factitious alteration of the parts, they may be rendered incapable of exercising their proper functions.

(a.) *Affections of the penis—Deficiency.*—It may happen that the penis is wholly or in part deficient. There have been instances of this part being totally absent from birth, and numerous examples of its removal by wounds, disease, or surgical operation. When the organ is completely absent, there can be no intromission, and, to all intents and purposes, the individual must be accounted impotent; unless, indeed, we understand that term in some other acceptation than that in which it is usually employed.

I have been made acquainted, through the kindness of Mr. Whitmore, of Cold-bath-square, with the particulars of a curious case which came under his observation. In the year 1823, a man, of the name of Staunton, lost his penis: it was amputated by his wife, one night, while he lay asleep by her side in bed;—the part was cut clean off at the root. Yet this very man was brought up, about three years ago, before the magistrates at Union Hall, on a charge of bigamy and filiation. He was presumed to have become the father of a child after his mutilation. This, at least, was the impression of many who knew the individual. But Mr. Whitmore thinks it doubtful that the child was begotten, however it might have been born, after the outrage. If the child's age could be ascertained, it would settle the question.

But where any portion of the organ is present, we must be cautious how we pronounce against its efficiency. It is an ascertained fact that impregnation may be effected if the semen be only deposited within the very orifice of the vagina. Hence it would be rather precipitate to assume the impotence of a person well formed in other respects, who should appear, on examination, to have merely a portion of the corpora cavernosa and urethra, yet capable of being introduced within the external parts of the female. The glans penis is known, in frequent instances, to have been

lost from accident or disease, yet the individuals so affected have had sexual intercourse as usual. "Piazzoni relates a case," says Dr. Paris, "where both the corpora cavernosa were destroyed, but, as the canal of the urethra was preserved, the person could perform the act of coition without difficulty. Frank also states an instance in which so considerable a portion of the penis had been carried away by a musket-shot, that, when the wound healed, the organ remained curved, and yet it remained adequate to the performance of its functions."

I am indebted to Mr. Whitmore, who so obligingly communicated the case already quoted, for the two following also, which are, perhaps, not less curious:—"I have had two other cases where the loss of the penis had been sustained. One occurred in one of my parish patients, who died a few weeks ago: he left a fine family of children; his penis had been amputated many years since. The other case occurred in a boy about fifteen, from the bite of a stone-horse. I remember, while under treatment, he sent word to his sweetheart, "not to fret, for that he should be able to stump her yet!" These were his words; doubtlessly a faithful indication of his feelings and intentions.

Hypospadia and epispadia.—Another imperfection of the penis, which might seem likely to interfere with the generative act is, that irregular opening of the urethra constituting hypospadia, or epispadia*. But persons of such a conformation have not only not been impotent, but unquestionably prolific. Belloc gives a curious instance of a hypospadian who had four children; two of them having precisely the same malformation as their parent.

Even where the orifice of the urethra has been as low down as the root of the penis, impregnation has been effected, with the aid of an artificial contrivance. At least we have it, on the authority of Sir Everard Home, that John Hunter gave certain directions to a person so affected, which were attended with complete success.

An hypospadian assisted by Mr. Hunter.—This celebrated case is so often referred to, that it may be as well to state it to you in the words of Sir Everard Home himself, who originally published it in the Philosophical Transactions for the year 1799. The paper in which Sir Everard (then Mr.) Home relates the case, is one on the subject of hermaphroditism in a dog; and he introduces into it several very curious observations on reputed hermaphrodites of various species; and, among the rest, he notices those malformations in which inexpert observers have found rea-

sons of their own for supposing the presence of hermaphroditism. Sir Everard tells us that the gentleman in question had an aperture in perinæo, which it was found impossible to stop; for as the canal of the urethra was continued to the external orifice of the glans penis, the attempt to close the anomalous passage was made, but in vain. "Under the circumstances," says Sir Everard, "the person married. When he had connexion, the emission was complete; which proved that the testicles were perfect, but the semen always passed out at the perinæum. The late Mr. Hunter was consulted to remedy, if possible, this inconvenience, and to enable the person to beget children. After the failure of several modes of treatment which were adopted, Mr. Hunter suggested the following experiment. He advised that the husband should be prepared with a syringe fitted for the purpose, previously warmed; and that immediately after the emission had taken place, it should be taken up by the syringe, and injected into the vagina, while the female organs were still under the influence of the coitus, and in the proper state for receiving the semen. This experiment was actually made, and the wife proved with child. Upon a subject of this kind, it is proper to speak with caution; but from all the attending circumstances, no doubt was entertained by Mr. Hunter or the husband, that the impregnation was entirely the effect of the experiment. Spallanzani's experiments "upon animals," adds the writer, "were made several years after this proposal of Mr. Hunter was attended with success*."

Phymosis and other affections.—But to return to the imperfections of the male organ. The part may be affected with congenital phymosis, and this, unless an operation be performed, will certainly prevent the generative act. It was a custom, in ancient times, to produce an artificial phymosis by *infibulating* the prepuce of young slaves. The method was effectual in precluding sexual intercourse, and was adopted in order to keep them in high health and beauty: perhaps also to restrain them from vicious indulgences.

The muscles of the penis have sometimes been affected with paralysis; and while such an affection lasts, it must be considered as inevitably entailing impotence. The cause of such a condition may generally be traced to some disturbance of the nervous system, through which channel alone the remedy must be supplied. Priapism frequently occurring, severe strictures, and certain diseases of the

* See Lecture V., p. 132, *ante*.

* Phil. Trans., 1799, p. 161—2.

prostate gland, may also be considered as occasional causes of impotence: but as they are all more or less remediable by art we must take care not to form too hasty a medico-legal diagnosis.

(B.) *Affections of the testes.*—The imperfections hitherto noticed have all belonged to the penis. We have now to notice another cause of impotence, arising more or less from deficiency or disease of the testes.

Where the testes are wholly absent—removed by an operation, or carried away by some injury—the impotence of the party is obviously to be inferred; but in such case, the marks of castration, or the cicatrices from the injury or wound, ought to be discernible. Where the testes are simply not found in the scrotum, and there is no appearance of their removal, we must inquire further before we hazard an opinion. These organs may not have descended into their usual place, nor have passed the abdominal rings: they may still be in the abdomen (persons so affected are called *Cryptorchides*), where their anomalous situation during adult life, is, in the opinion of some, so far from being an impediment to the reproductive function, that it is rather conducive to their efficiency. This, however, is very doubtful.

If the testes have wasted away, as they sometimes do from disease—elephantiasis, for example—proofs of that fact will not be wanting in the individual: the characters of manhood will be more or less absent; the sexual appetite will be lost; and, in short, it will be a case of incurable impotence.

The same result must have befallen those individuals whom it was the custom to emasculate in childhood by bruising the testicle, as is still done with deer and other animals. The injury deprives the parts of their organic life, they become atrophied, and unsuited to perform their natural functions.

As to castration, it is well known that it does not immediately or necessarily entail impotence. Much will depend on the extent to which the operation is carried, and the time of life at which it is performed. If both testes be removed in infancy, or boyhood, the individual never acquires a masculine character—he cannot but be impotent; but where castration has been effected in an adult, the semblance of virility will still be retained; though it is said that the beard will become more thin and scanty. Persons of this description are known to retain a certain imperfect power of sexual intercourse, attended with the discharge of a mucous fluid from the vesiculæ seminales, and probably from the prostate. But it is out of the question that they should ever be pro-

lific, unless the generative act should be accomplished some short time after emasculation; for there may still be some semen in the vesicles. Otto, indeed, mentions one case in which he found plenty of apparently good semen in the vesiculæ seminales of a man who had castrated himself a year before, in a fit of melancholy.

In cases where one testicle is left (persons so affected are termed *Monorchides*), no matter how the other have been lost, we must cautiously abstain from pronouncing against the generative faculty of the individual. In fact it has been proved, in numerous instances, that *two* testes are by no means essential to potency, notwithstanding that the parliament of Paris, in 1665, decreed that the marriage contract should not be held valid unless *two* testes were producible!

Remarkable case of Count Sorlisi.—It was about this very date that the circumstances of a celebrated case were much discussed in Germany: I allude to the marriage of the Count de Sorlisi. Valentin, in his *Novellæ Medico-Legales*, gives a full account of the case, under the title of *Conjugium Eunuchi*; and Dr. Ferriar has presented us with a very interesting abstract of it, in his *Illustrations of Sterne*. I shall take leave to give you a brief summary of the principal facts.

Bartholomew de Sorlisi, a young nobleman, held a commission in the army of Charles XII. of Sweden; but his military career was brought to a close by a catastrophe which befel him at the battle of Fühnen: he received a musket-shot, by which he was deprived of the testes—*bombardæ ictu eviratus est*. The wound was healed; but disgusted with the chances of war, he retired to an estate in Pomerania, where he endeavoured to forget his misfortune in the occupations of a country life. Here he became acquainted with a family in which there was an only daughter, Dorothea Elizabeth Lichtwer, a beautiful girl of sixteen. Of her he became deeply enamoured, and the attachment being mutual, he was induced, forgetful of his situation, to make proposals of marriage. These were readily accepted, and the time fixed.

But unfortunately some of the lady's relations were opposed to the match, chiefly on account of a difference of religion between the parties, the Count being a Roman catholic; this, however, might have been got over, had not an unexpected piece of treachery thrown Sorlisi into the hands of his enemies. It appears that in unsuspecting confidence he consulted the physician of the Lichtwer family, and disclosed to him the secret which preyed upon his mind. The doctor, forgetful of his inaugural oath, shamefully betrayed his patient, and furnished the discontented party with

facts which seemed sufficient to overwhelm the object of their dislike. Sorlisi faced the storm gallantly, and by exposing his life in some duels, soon procured an exemption from further private insults.

It should be mentioned that circumstances had by this time gone so far, that it was necessary for the Count to explain his situation to his intended bride, and her only surviving parent. How this delicate task was accomplished, we are left to imagine: but the result is known; Madame de Lichtwer was inclined to give up the match, but Dorothea declared that no misfortune could affect her attachment, and that she was determined to pass her life with Sorlisi under every disadvantage. The parties were now betrothed with the mother's consent. How to complete the marriage was the question; for already the theological faculties had taken alarm, and murmured so loudly against the proposed scandal, that it was evident no clergyman would venture to solemnize their nuptials.

Sorsli was obliged to draw up his case, and submit it to the ecclesiastical consistory of Leipsic; the answer of the consistory was favourable and very fair, though founded on a curious casuistical distinction. It was stated that the Count's impotence was not of such a nature as to prevent the generative act, but only the effect: *non quidem talem impotentiam et inhabilitatem quæ generationis actum, ut scholastici loquuntur, sed generationis effectum tantum impedit.*

After considerable delay, the marriage was at length permitted to be privately performed. But the matter was by no means suffered here to rest. The supreme ecclesiastical consistory, which had hitherto taken no cognizance of the case, interposed, and demanded that the parties should be separated. Madame de Sorlisi, too, who protested that she would rather die than forsake her husband, was interdicted the sacrament.

The various theological faculties of Germany were now consulted; and nothing could exceed the zeal of those learned bodies in dissecting and discussing all the various distinctions that could be made out respecting the case. It would seem, indeed, that to counteract the practice of vice, they had thought it necessary to be completely masters of every vice in speculation.

The faculty of Hasse-Giessen were for dissolving the union immediately, for the lady's sake: for they thought that she must be tormented excessively by her husband, whom they compared, in the language of St. Basil, to a bull with his horns cut off, *instar bovis cui cornua sunt abscissa, imaginem impetus facere, incredibilem vesaniam spirando.*

The faculty of Strasburg held that so damnable a connexion could not be tolerated, approved, or defended: they said that the lady, in desiring to live with her husband, committed a mortal sin; and finally exclaimed, that if the young couple did not consent to separate, they ought to be banished from a land of piety.

In the faculty of Jena the matter was discussed with more mildness. They thought, however, that Sorlisi should rather have married some old woman, as it was only society he could have wanted; and they, therefore, were of opinion, that a separation should take place.

The Königsberg faculty thought that some regard should be paid to the contentment of the lady, and that the parties should be allowed to remain together. On the same principle, the faculty of Greifswald opined that, as the lady had got into the scrape with her eyes open, she should abide by the consequences, though it did not seem to them to amount to a mortal transgression.

There were, besides these thundering bodies, several individual skirmishers in the field. A Dr. Bulaeus took part with Sorlisi, and showed that there was nothing so very scandalous and alarming in the marriage. He censured the scandal that arose out of the discussions which had taken place, and proved on the whole, that excepting the certain prospect of sterility, there was nothing to be complained of, while many other matches, equally objectionable in that respect, were often formed between persons of very unequal ages.

But others maintained in round terms, that it was a match brought about by the Devil himself; that it was absurd to give more credit to the fancies of a raw girl than to the grave opinions of a host of bearded divines; and one advised that the lovers, instead of being allowed to marry, should have been cudgelled out of their mutual affection. This last polemic literally called out for clubs; "*ad baculum, ad baculum, quo pruritus extinguitur!*"

To conclude this chequered history, the Consistory of Leipsic, in May 1668, two years after the commencement of the proceedings just detailed, formally declared that the marriage ought to be tolerated, and the parties freed from further annoyance. The Elector, however, appended a clause to this decision, that the case was not to be made a precedent, and that no future indulgence of the same kind should be permitted.

I shall only add that this narrative was the one on which Sterne so wittily founded Uncle Toby's wound in the groin, and the consequent doubts of Widow Wadman. But independently of this, the distresses of the Abelard and Heloise of Germany

seemed deserving of being better known, especially as they constitute a decidedly medico-legal case.

2. Moral Causes.

It happens not unfrequently that although there be no external defect of structure, still the individual is really impotent. In such circumstances, however, the inability is generally functional and temporary. The case has often been quoted, which John Hunter relates in his treatise on the Venereal. A gentleman consulted him, complaining of absolute inability to have sexual intercourse; upon which the sagacious surgeon, suspecting the cause, as there was no apparent physical reason for impotence, made him promise upon his honour to pass six nights with a young woman, without attempting to have any connexion with her, however strong might be his desire. The spell was broken, the current of the patient's thoughts being changed: instead of anxiety about his supposed impotence, he soon began to apprehend that he could not restrain himself so as to keep his word of honour passed to Mr. Hunter; and such proved to be the case.

Fascination, fear, and other affections.—In times of superstition, such a state of impotence was always sure to be attributed to the influence of magic; and you will see in Montaigne what a remarkable cure that acute essayist effected on a friend of his, by supplying him with a pretended counter-charm. Cases also have often been met with, in which the doubt of impotence has led to the fact, and the unfortunate dupes of their own suspicions have sought a termination of their distresses in suicide. On the other hand, excessive desire is a frequent cause of inability; but it seldom lasts long, and can prove but a temporary impediment.

Habits and modes of living.—Certain habits, such as frequent intoxication, and vicious indulgences of various kinds, often produce such a want of nervous energy, and so debilitating an effect on both mind and body, as to render the individual incapable of exercising the generative function. Strong narcotics, also, such as opium and tobacco, and according to some—Metzger among the number—coffee, when taken immoderately, are said to have the same effect. An odd story is told by Murray, in his *Apparatus Medicuminum*, of one of the wives of the Sultan Mahmud, who, on looking out of her window one day, saw some grooms proceeding to castrate a fine horse: she called aloud to them to forbear, and to give the animal coffee, for she had observed the effects of that beverage upon her husband! Camphor also was long believed to possess

anaphrodisiac qualities, or, as the verse has it,—

“Camphora per nares castrat odore mares.”

Sir Thomas Browne combats this notion as a vulgar error.

Partial impotence.—It is a well-known fact that men may become impotent with regard to particular females, while with others they possess their full powers. The law recognises such a form of inability, which it terms *impotentia quoad hanc*, and a divorce was granted in the Earl of Essex's case on this ground, Lady Essex charging his Lordship with impotence, and he confessing himself so with regard to her. Some other curious particulars connected with this case I shall hereafter have to notice.

The impotence *quoad hanc*, can, in general, be accounted for; and will probably be found in most cases to arise from one or more of the bad qualities summed up by Baumer as the extinguishers of affection—*Morositas, contemptus, ira, tristitia, corporis immundities ac factor, venerem primario supprimunt*.

A very singular case was published at Venice, in the year 1815, and was much discussed in the German journals soon after. It was a marriage which was dissolved the day after it was celebrated. The bride, a lady of 27, much admired for her beauty, was most unexpectedly found to have her person covered from the breast to the knees with a profusion of black, thick, and bristly hair: she was, in fact, compared to a black poodle in those parts; and it was held to be a sufficient ground of divorce.

A remarkable blunder, which had well nigh been attended with serious consequences, was once committed in our ecclesiastical courts, by the authorities there pronouncing too absolutely in a question of impotence. This was in the case of one Bury, who was divorced a *vinculo matrimonii* for frigidity or “perpetual impotency of generation.” He afterwards married another wife, and had children by her; upon which it was urged that the church having been evidently deceived, the divorce thereupon was null; and if so, that the second marriage was unlawful, and the issue illegitimate. But the courts of common law decided, that since there had been a divorce for impotence, it was clear that each party might lawfully marry again; and though it should be allowed that by reason of the error of the church, the second marriage was voidable, yet till it were actually made void, it remained a marriage, and the issue were to be deemed unlawful.

Similar cases have occurred on the continent, and have led to much casuistical discussion,—perhaps also to some scandal.

A grand controversy was, whether a man, who had been divorced for impotence through sorcery, and had married again and had children, might, on the death of the second wife, be claimed by the first? The canonists thundered against each other, as they took different sides of the question. In truth, ever since Sanchez wrote his great work, *de Matrimonio*, the discussion of all possible cases in which capability may exist at one time and impotence at another, has been a favourite occupation of the casuists; and it is said that some of their refined hypotheses never entered into the imagination of any other people in the world, than themselves.

CASES OF POISONING

BY

OPIUM, AND BY BELLADONNA.

To the Editor of the Medical Gazette.

SIR,

Two cases of poisoning by laudanum having recently been brought to St. Thomas's Hospital within twenty-four hours of each other, and as the parties were nearly equal in age, and similar in physical power, while the quantity of the opiate they had taken, and also the time that elapsed before they were submitted to medical treatment, was almost precisely the same, it was thought that so fair an opportunity for determining the effects of bleeding in these cases ought not to be neglected. The cases, therefore, were treated alike in every respect, with the exception that one was bled, while in the other that operation was omitted. From the narration of the cases, it will be seen that the latter recovered in a much shorter time, and with fewer distressing symptoms, than the former; a fact which, although it might have been predicated from the known laws of poisons, remained still to be proved by experiment; and as the cases in this point of view are important, I shall feel obliged by your giving them insertion in your valuable journal.

I inclose also a case of poisoning by belladonna, in which the little patient was bled; but it will be seen that after the bleeding her recovery was very doubtful, and that the symptoms were

so imminent, that I should hesitate in having recourse to that operation in any similar case.—I am, sir,

Your obedient servant,

HENRY BULLOCK.

St. Thomas's Hospital,
Nov. 14, 1836.

CASE I.—*Poisoning by Opium.*

Sarah Todd, 21 years of age, and of robust health, was brought into St. Thomas's Hospital at four o'clock in the afternoon of Wednesday, Oct. 5, 1836, having taken an ounce of laudanum two hours previously.

It was stated, that half an hour after she had drunk it she complained of sickness and of excessive thirst; that at length she became drowsy, and ultimately insensible. On being taken to the ward she lay comatose, with her pupils contracted and insensible to light, her countenance livid, her respiration slow, almost imperceptible; the surface of her body cold, and her pulse slow and feeble; and what was remarkable, was the great relaxation of the muscular system.

Her stomach was immediately emptied by means of the stomach-pump, and then washed out by the repeated injection of large quantities of warm water. An emetic dose of the sulphate of zinc was next given, which excited vomiting several times. She was then made to walk round the squares of the hospital, supported by two men, resting at intervals. At seven o'clock we were gratified by her becoming sensible, when she complained of headache, of lassitude, and of drowsiness. Twelve o'clock arrived, and as the symptoms remained much the same, she was bled to twelve ounces, and a mustard cataplasm applied to the stomach, which had no sooner drawn, than the same forced activity was directed to be continued, while lemon-juice and strong coffee were administered at short intervals. The patient was in this manner kept moving for twelve hours, when all the symptoms of poisoning having subsided, I allowed her to go to bed, with mustard cataplasms placed on her feet as a precautionary measure.

On Thursday she had some refreshing sleep, but as late as Friday she complained of headache, was feverish, and her tongue was dry, while the pupil was but slightly acted upon by light. On Saturday, however, the symptoms con-

siderably abated, so that on Monday she left the hospital quite well.

CASE II.—*Poisoning by Opium.*

Jane Morgan, 20 years of age, a strong and equally healthy person with Sarah Todd, in a fit of jealousy, took an ounce of laudanum at 11 o'clock on Thursday morning, October 6th, 1836. About an hour and three quarters afterwards she was brought to the hospital, when it was stated that almost immediately after having taken the opium, she complained of headache, but subsequently she fell into a stupor, and at the time I saw her, she was completely insensible and comatose, with her eyes fixed, the pupils contracted, and altogether unaffected by light; her breathing was also slow and stertorous, her pulse feeble, scarcely to be felt, the surface of the body cold, her countenance bloated, and no stimulus I could employ had any effect in arousing her. Without loss of time, I introduced the stomach-pump, evacuated the contents of the stomach, and cleansed it by means of repeated injections of warm water; copious vomiting was next produced by a solution of the sulphate of zinc, and this having subsided, she was, as in the former case, kept constantly moving, by the assistance of two men. At 8 o'clock she had become so far sensible as to recognize her friends, and to be able to speak, though still overpowered by sleep, and suffering intense headache: a mustard cataplasm was then applied to the epigastrium, and immediately afterwards directions were given to make her drink freely of strong coffee and acids, and to persevere with the same forced exercise. At 12 o'clock these means had been so far successful, that she was perfectly sensible; and as all the urgent symptoms, except severe headache, had disappeared, she was put to bed, and mustard poultices ordered to the feet. During the night she slept but little, and on Friday morning she expressed herself as being quite recovered. Certainly not a single distressing symptom remained, for even the iris acted well; she left the hospital, quite well, on Tuesday.

Many physicians have advocated the treatment by bleeding, and speak of its universal success. Formerly, within my own recollection, bleeding was the practice of this hospital; and I am informed, on good authority, that some

years since, it was received as a general principle, and constantly acted upon. This doctrine, however, having been lately considered untenable, and at variance with all the known laws of the action of remedies upon the system, and bleeding consequently suspended, the results have been infinitely more successful, and the convalescence completed within a much shorter time.

I would not be understood to intimate that bleeding in all cases in which opium has been taken is prejudicial, or inadmissible, but as these cases singularly illustrate the great principle, that bleeding is not the rule of treatment when the system is under the influence of poison, I have thought that the publication of these might induce others to abandon, in similar instances, the use of the lancet, and to report the results.

Poisoning by Belladonna.

September 23, 1836. — Ann Forth, a girl nine years of age, was brought to St. Thomas's Hospital at night, by her parents, who stated that she had been poisoned by belladonna, having, in the evening, ate portions of the bark, and masticated the root of that plant. Two hours after, she was taken with a feeling of sickness, a loathing of food, a distressing sense of lassitude, and dryness of the throat. At nine o'clock, or four hours after the accident, delirium came on, which lasted about an hour, and was succeeded by an irregular convulsive action of the whole muscular system. About this period I saw her, when she was in a state of complete insensibility, approaching to coma; her face was distorted and pallid; her eyes protruded and suffused, the lids separated, the pupils fully dilated, and scarcely affected by the action of light; whilst there were frequent convulsions of the muscles of the face, as well as of the extremities, for the angles of the mouth were retracted and agitated; the lower jaw was alternately fixed and trembling. In addition to these striking phenomena, the surface of the body was cold and clammy, the pulse small, rapid, and intermittent, and she had sunk into a state of lethargy so absolute that it was impossible to rouse her. Assisted by my friend, Mr. Stone, of Christ's Hospital, the stomach-pump was immediately employed, warm water plentifully injected, and the contents of the stomach in this manner removed. This was no sooner

effected than an emetic dose of sulphate of zinc was injected into the stomach, and the treatment was so successful that the convulsions subsided previous to withdrawing the tube. Enemata of warm water were now administered, a mustard plaster applied to the nape of the neck, and I directed that she should be sharply shaken and be kept in constant motion about the squares of the hospital; lemon-juice and water being freely supplied her. By one o'clock, A.M., the child having frequently vomited, had decidedly less stupor; and although almost overpowered by the tendency to sleep, yet the iris acts perceptibly on the impression of light. The unfavourable symptoms were, her pulse continuing intermittent, though of more volume than before; the alvine evacuations and urine passing involuntarily.

4 A.M.—Has continued to improve, and attempts to answer questions; complains of headache, and of total blindness; pulse 112, regular, and stronger. The power of recognition having returned, she was now bled to six ounces, mustard cataplasms applied to the legs, and the same forced activity to be continued; for so imperative was the disposition to sleep, that, if allowed to remain quiet only for a minute she fell down in a profound sleep. At 8 A.M. she was quite sensible, able to walk alone, and her eye being less prominent, and the pupil sufficiently obedient to the action of light, the power of vision was restored, though she saw but dimly. As she had now been in a state of constant motion for fourteen hours, she was permitted to go to bed, with mustard plasters applied to the feet, and an aperient medicine. From this period to the time of her leaving the hospital, on the 8th of October, she gradually recovered; making occasional complaints of headache, soreness of the eyes, and intolerance of light; which, however, at length ceased.

ON THE NERVES WITHIN THE ORBIT.

To the Editor of the Medical Gazette.

SIR,

In the communication by Mr. Thurnam of last week, he admonishes physiolo-

gists not to neglect the study of comparative anatomy; and after this salutary advice, proceeds, with much complacency, to state that a peculiar distribution of the nerves in the orbit of certain of our domestic animals, has been entirely overlooked by the modern writers who have treated of these nerves. Upon this ground he makes sundry reflections on the inconvenience of proposing theories which do not admit of general application, and even calls upon us to reject every explanation of the uses of the nerves in the orbit that has hitherto been started.

One would naturally conceive, that before coming forward with such sweeping denunciations of neglect and error, Mr. Thurnam would have taken some pains to become acquainted with the works of the authors whose opinions he criticises. The fact in comparative anatomy which he announces in this ostentatious manner, is the distribution of the sixth pair of nerves in quadrupeds to the conoid or retractor muscle—that muscle which, arising at the back of the orbit, embraces the optic nerve, and is attached to the posterior part of the eyeball. Mr. Thurnam informs us that one great authority on the nervous system, Willis (from whom we continue to take our nomenclature of the nerves), was familiarly acquainted with this distribution; but he asserts that the fact was completely lost sight of by subsequent anatomists and physiologists; and he claims some credit, it would appear, for having revived our knowledge on this point. One of the gentlemen whom he singles out in particular, as having been guilty of the negligence imputed to physiologists generally, is Sir Charles Bell; and from the short and positive manner in which he dismisses this author's reasonings on the nerves within the orbit, we should be led to conjecture that Mr. Thurnam had perused his works with the greatest attention. Now it may astonish your readers to learn, that although Sir Charles Bell's writings are thus held up to view as based on imperfect observations, they contain, nevertheless, an accurate statement of the fact to which so great importance is attached; and not only is the distribution in question conspicuously brought forward by the author, as harmonizing with his other views, in no less than two of his best-known works, viz. the "System of Anatomy" (vol. ii. p. 504),

and the "Nervous System" (p. 215), but to shew how he estimated the fact, it is made the foundation of an original theory, of which Mr. Thurnam proves himself entirely ignorant, to explain why the sixth nerve in man should supply the abducens muscle of the eye exclusively.

I may remark, in addition, that it is acknowledged by Sir Charles Bell that the observation was obtained by him from Willis, whose character as an accurate anatomist he takes the opportunity of praising in the highest terms.

It is not, I presume, expected that I should here enter into an explanation of the theory alluded to, as proposed by Sir Charles Bell, in connexion with this piece of anatomy. I have done enough in shewing that, contrary to Mr. Thurnam's representations, he has not altogether neglected the comparative anatomy of the eye. I might, indeed, prove, that so far from such being the case, he has gone further into the inquiries bearing upon this subject than was contemplated by this ingenious comparative anatomist himself. Let me ask, why has Mr. Thurnam never once alluded to the mechanism for protruding the third eye-lid, or how, in those animals that possess the retractor muscle, and to which the sixth pair is distributed? Does he know that quadrupeds have a third eye-lid? By neglecting this apparatus, nothing can be conceived more fanciful or absurd than the use which he has attributed to the retractor muscle; following, I ought to say, the authority of Willis. It may, perhaps, be quite just to recommend this old English anatomist for the accuracy of his anatomy; but it was scarcely to be expected that, in the present day, he would be readily accepted as an authority in physiology. What, then, is the opinion that Willis entertained of the proper function of the retractor muscle, and to which Mr. Thurnam gives his especial approbation? He considered that as this muscle is found in animals which feed with their heads hanging low, it was added for the sake of retaining the eye-ball securely in the socket—for preventing the globe of the eye slipping bolt out, when these animals were grazing; an accident which he supposed was likely to occur, even although this organ is held in its place, as we know, not only by means of the optic nerve, and the four strong recti

muscles, but by the two eye-lids also, which could close upon the eye, and hold it in, if ever the necessity arose for preventing its dropping out*! In token of his admiration of this notable theory, Mr. Thurnam speaks always of this muscle as the "suspensory" muscle.

I have the honour to be,

Your obedient servant,

ALEXANDER SHAW.

Middlesex Hospital Medical School,

REMUNERATION OF MEDICAL WITNESSES.

To the Editor of the Medical Gazette.

SIR,

THE particulars of the accompanying medico-legal case were furnished to me by a friend, who acted as witness on the occasion. I have appended to it a few remarks on the remuneration of witnesses, which may possibly interest those of your readers who are engaged in the practice of medical jurisprudence.

I am, sir,

Your obedient servant,

ALFRED S. TAYLOR,

Lecturer on Med. Jur. and Chemistry
in Guy's Hospital.

Nov. 14, 1836.

A coroner's inquest was held, a few months since, upon the body of a child, which was found under such circumstances as to lead to the suspicion that it had been murdered at its birth. There was no evidence to support the charge of infanticide against the mother; but there were reasons to believe that she had concealed the birth, and had thereby rendered herself indictable for a misdemeanor. The jury returned a verdict of "*found dead*." The question of concealment being out of the jurisdiction of the Coroner, that functionary transmitted a copy of the depositions, taken before him, to a police magistrate. The different witnesses, including the gentleman who had ably conducted the medico-legal investigation, were subsequently examined by the magistrate,

* Observare est quod quadrupedes, qui oculos in terram pronos ac pendulos gerunt, musculum peculiarem habent, quo oculi globus suspenditur, et ne pondere suo extra ossis orbitam dilabi aptus sit, sustentatur.—Willis.

and were by him bound in the usual recognizances to prefer a bill of indictment against the prisoner at the sessions. The case was soon afterwards tried, and the prisoner was acquitted, some circumstantial points having been adduced in her favour.

On the medical witness applying to the court for remuneration for his trouble and loss of time, he was informed that it had no power to order payment of expenses in that particular misdemeanor. He was then referred to the act, 7 Geo. IV. c. 64. s. 23, which allows the payment of expenses to prosecutors and witnesses only in certain misdemeanors there enumerated: "concealment of birth" is not among them.

The injustice to which the witness was subjected in this case will appear more striking, when it is considered—that he had already conducted a troublesome investigation before the coroner, having inspected the body of the child, and performed the usual experiments to determine whether it had respired or not, for which, by 6 and 7 Will. IV. c. 89, s. 5, he being connected with a parochial infirmary, and the case being a parish case, could receive no remuneration;—that he had afterwards to appear and confirm his evidence before the police magistrate, for which, even had the misdemeanor been one of those named in the statute 7 Geo. IV. c. 64, he could have received no fee, since sec. 23 positively forbids the payment of expenses and compensation to witnesses, for attendance before the examining magistrate;—and that subsequently, at a great sacrifice of time and personal convenience, he was compelled to attend and give evidence on the trial of the prisoner at the sessions, where he had to learn the existence of this *casus omissus* in the statute.

It appears to me that we have here an instance of defective legislation which must often press particularly hard upon members of the profession, and a grievance which ought, as a matter of common justice, to be speedily removed.

For the information of those practitioners who may not have the statute by them, it may be stated that the following are the misdemeanors for which alone the expenses of witnesses are allowed:—Assaults with intent to commit felony; attempts to commit felony; riots; misdemeanors for receiving stolen property, knowing the same to have

been stolen; assaults upon peace officers in the execution of their duty, &c.; assaults committed in pursuance of any conspiracy to raise the rate of wages; knowingly and designedly obtaining property by false pretences; wilful and indecent exposure of the person; wilful and corrupt perjury; subornation of perjury. The only two cases in the above list which are likely to require professional testimony, are—assaults with intent to commit felony, and attempts to commit felony; and in these, it must be remembered, a witness is not entitled to any remuneration for the evidence which he may give before a magistrate. Besides, whatever trouble and inconvenience he may be exposed to, should the prosecutor remove the indictment by *certiorari* into the King's Bench, and the case be tried at Nisi Prius, he is not entitled under this statute to any fee even for his evidence at the trial of the prisoner*.

The refusal of his expenses to a medical witness attending before an examining magistrate to give evidence in a case of misdemeanor, is as much a matter of specific injustice, as it was formerly, in the case of his attendance before a coroner. The wilfully throwing of sulphuric acid or other corrosive substances, on the person, is, for example, a misdemeanor (in England) which might require as careful a chemical analysis, on the part of a practitioner, before a prisoner could be committed by a magistrate, as any case of fatal poisoning falling under the jurisdiction of a coroner. On what principle, therefore, does this statute prohibit the payment of expenses to witnesses, without any reservation in favour of those whose time is so often, in other ways, gratuitously sacrificed to the public good? There are other misdemeanors, altogether omitted by this statute, in which, as in the case of "concealment of birth," a practitioner must give his professional testimony before a magistrate, and at the sessions, without, in either case, receiving any fee or remuneration whatever.

In charges of felony before a magistrate, a medical witness is, by sec. 22, entitled to his expenses for attendance at the examination, provided he obtains a certificate from the magistrate before

* *Rex v. Johnson*, R. and M. 173; Archbold's *Crim. Pleading*, 140.

the trial; but the granting of this certificate is left optional with the magistrate. Here is a very singular legal distinction. To the medical practitioner it can matter but little whether the crime of which the prisoner, against whom he appears, is accused, be a felony or a misdemeanor: the sacrifice of time on his part, and the knowledge required for conducting the medico-legal investigation, will be much the same in the two cases. Indeed, the attendance before a magistrate in a misdemeanor, may often give rise to more trouble than in felony; and yet the law decrees remuneration to the witness, not according to the trouble incurred, but according to the degree of crime of which a prisoner may have been guilty!

It would be occupying too much of your valuable space to pursue this subject further; but I think these observations will suffice to show that some additional legal provisions ought to be made, to remove what must be regarded as an oppressive evil.

ON THE
USES AND ABUSES OF ALOES.

To the Editor of the Medical Gazette.

SIR,

WHEN you can afford space in your excellent journal, I shall feel obliged by your admitting the following observations on the use and abuse of aloes.

I remain, sir,
Your obedient servant,
EDWARD GREENHOW, M.D.

North Shields, Nov. 8, 1836.

There is no substance which enters so largely into the composition of aperient medicines, as aloes, and none, perhaps, for which we should find it so difficult to procure a substitute, the dose required being so minute, that it is readily administered in a small bulk; and its action being confined to the large intestines, little or no derangement of the alimentary canal is occasioned by its operation: such at least is the case when used with discretion; but I am prepared to shew that great and serious mischief often results from the inordinate, or too long-continued use of aloes, more particularly when taken habitually, as has

become too commonly the case, without the knowledge or supervision of a medical man, the non-medical part of the community being little aware that any ill effects can attend the use of a remedy so universally employed.

Medical writers describe aloes to be a stimulating cathartic bitter, which is said to act by increasing the muscular or peristaltic action of the intestines; but it evidently acts also by irritating the mucous membrane of the intestines, and producing a larger secretion; this is manifest from the large quantity of mucus often passed with the evacuations when aloetic aperients have been exhibited. Authors differ considerably as to the doses which ought to be given; Lewis mentions 3ss., or ℥ij., when we wish to purge effectually: "at the same time," he says, "it occasions commonly great irritation about the anus, and sometimes a discharge of blood;" he then goes on to say, "in smaller doses, as ten or twelve grains repeated once or twice a day, it not only unloads the first passages, but attenuates and dissolves viscid humours in the remote parts, warms the habit, quickens the circulation, and promotes the menstrual and hæmorrhoidal fluxes: its continued use renders the blood sensibly more fluid, as appears on venesection. Cullen says, it empties the great intestines, and it is remarkable it does this in a very small dose. I have known innumerable instances of persons who very constantly obtained this effect from one or two grains of aloes. Paris states the dose to be from five to fifteen grains, and says, no greater effect is produced by a large dose, than by one comparatively moderate. Braude states the dose to be from two to ten or fifteen grains. Pereira says, "taken internally in small doses, aloes acts as a tonic to the alimentary canal, assisting the digestive process, strengthening the muscular fibres, and promoting the secretions, especially that of the liver, which organ it is thought specifically to influence: in large doses it acts as a purgative." I will now detail the result of my own observations during several years, in a great number of cases, in which aloes was given in every variety of dose; and I have almost uniformly found that very small doses have answered all the purposes to be obtained by its use, viz. substantial feculent evacuations, attended by little or no irritation; and for this

purpose from two to five grains will be found sufficient: when administered in larger doses, it is apt to occasion griping, heat about the anus, and, if long continued, hæmorrhoids; it also loses its effect of properly emptying the large intestines, producing frequent small evacuations, consisting principally of mucus, and attended with tenesmus, the abdomen being at the same time distended and tender, the patient complaining that "his bowels feel as if scraped;" the pulse is sensibly quickened, and a sense of constriction is felt about the head.

The long-continued use of aloetic aperients has a tendency to produce emaciation, and their action upon the bowels becomes capricious and uncertain, sometimes failing to produce any effect, and at others producing frequent small evacuations, as before described; the mucus being occasionally passed in long membranous bands, and sometimes in substances resembling pieces of flesh. I have also seen two cases, in which the mucus passed along with the evacuations had all the appearance of fat. It is not difficult to conceive that such a state of irritation, kept up for any length of time, or frequently recurring, must ultimately tend to some organic change of structure; and I think it highly probable that stricture in the rectum may sometimes have its origin in this source; and I have seen cases of enteritis which I believed to be traceable to the inordinate use of aloes.

It appears probable that aloes does not undergo any change or solution in passing through the alimentary canal, but that it becomes intimately blended with the dejecta; and when these are detained in the colon and rectum, that its stimulating effects are felt, causing these viscera to expel their contents, the unloading of which may give rise to a freer flow of bile. Aloes is undoubtedly useful as an emmenagogue; and, in combination with iron, is perhaps more to be relied upon than any other remedy. It is more difficult to account for its possessing any power over the action of the kidneys, yet such, I am convinced, is the case. I have many times found that when squill, along with other diuretics, failed to act, the addition of aloes has speedily produced a copious diuresis.

When aloes is given simply as an aperient, the best vehicle is some vege-

table extract, as gentian, or chamomile. Soap is objectionable, as impairing its purgative powers; so also do the aromatic oils to a certain extent; and alkalies are said to have a similar tendency. One or two grains of ipecacuanha combined with each dose of aloes, has the effect of diminishing, or often of altogether removing, its irritating effect upon the anus; and many persons labouring under piles are not only able to take it in this way with impunity, but with advantage.

When aloes produces griping, it may generally be remedied by the addition of a few grains of henbane extract, or extract of hops: the latter will be found preferable in most cases of dyspepsia. The effect of aloes is increased by comminution; therefore great pains should be taken in its preparation. Mastich is sometimes ordered in combination with it; I believe principally with a view to a more minute division of its particles. When aloes is combined with opium, its purgative properties are not generally lost, but only delayed, which makes it a valuable medicine to give in conjunction with that drug.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

Facts and Cases in Obstetric Medicine; with Observations on some of the more important Diseases incidental to Females. By J. T. INGLEBY, M.R.C.S. L. Senior Surgeon to the General Dispensary, Surgeon to the Magdalen Asylum, and Lecturer on Midwifery at the Royal School of Medicine, Birmingham. 8vo. pp. 206. Longman and Co.

We hail with pleasure the publication of practical works like this, for they denote a degree of intelligence and activity among our provincial brethren which deserves every encouragement.

Mr. Ingleby is a gentleman who has read, seen, and thought much, and who, to unwearied industry, has added the greatest ardour in the pursuit of professional knowledge. The present work consists of seven sections, a portion of which has already appeared in an es-

teemed periodical. They are all on practical subjects of much interest.

SECTION 1. On Puerperal Convulsions.—This is full of valuable matter: the only point about it which we regret, is the great want of clear and simple arrangement. The materials are excellent; they could scarcely be better; but they are spread out before us with so little attempt at classification as to render the subject much more obscure than it otherwise would be. The author mentions the arrangement made by Dr. Dewees, into three classes,—viz. the epileptic, the apoplectic, and the hysterical convulsions; and very properly adds the anæmic, as also the tetanic forms of puerperal convulsions. This latter form was described by Professor Naegele, many years before M. Velpeau had noticed it; also by Wigan. We could have wished to have seen these different forms discussed under separate heads; the distinctions would then have been more marked, and much more available to the student. The cases at the end of the section, individually, are excellent; they are described with clearness and precision, the practice is judicious and good; but collectively they are liable to the same objection of want of good arrangement. They are classed according to when they occurred—viz. firstly, those cases which took place during pregnancy and previous to labour; secondly, those previous to labour and terminating in delivery; thirdly, during the dilatation of the os uteri; fourthly, after the full dilatation of the os uteri; fifthly, after the birth of the child, and before the expulsion of the placenta; sixthly, after delivery. We cannot approve of this arrangement, because the treatment cannot be guided by the period at which the convulsions occur, but by the character of the attack.

SECT. 2.—On Malposition of the Uterus, Ovaria, Bladder, and Urethra, both in the impregnated and unimpregnated state, in connexion with retention of Urine.

The observations on retroversion of the uterus, and prolapsus vesicæ, are especially valuable and practical, and are illustrated by well-reported cases of much interest; those on prolapsus vesicæ during the latter months are well worthy the attention of practitioners.

SECT. 3.—On Obstructions in the Soft Parts to Progress of Labour.

Some instructive cases are given of tumefied labia, from varicose veins or extravasation of blood into the labial tissues. In a case of the latter kind, which the author describes, the tumor burst, and nearly a pint of coagula was removed by a pair of dressing forceps, through a laceration at the edge of the vagina. This affection does not occur frequently, and its extent is seldom so great as to become serious, as it rarely passes beyond the margin of the labium; even this, however, may become enormously tumefied, and where it bursts before the head has approached the os externum, may give rise to profuse hæmorrhage. This will cease, or at least be in great measure diminished, during the passage of the child; and if it returns afterwards to any extent, must be controlled by cold astringents, and other appropriate remedies. In some rare cases, the extravasation of blood into the cellular tissue has proceeded to an enormous extent, implicating the nates, and even the hips, in the swelling. The plan of puncturing the tumor, which Mr. Ingleby has found unsuccessful, is not adapted to all cases; and we are rather inclined to think that the opening which he made was not of sufficient depth and extent. Extravasations of this kind do not merely retard labour by the obstruction which they produce at the external opening, but also by the effect which they appear to have upon the pains: these not unfrequently cease as soon as the extravasation takes place, leaving the patient in a state of serious exhaustion.

Œdematous labia, especially where accompanied with anasarca tendency, may retard labour when the swelling is very large: the danger will chiefly depend upon the patient's general health. The author has recommended puncturing them with a fine curved needle, by which a load of serum is drained off, and much relief obtained. If labour be already commenced, we have scarcely any other means of relief in our power; but when the patient has still some days to go, warm stimulant fomentations will prove of great service. The *species aromatica* of the Prussian and other pharmacopæias soaked in some hot wine, will, in many cases, speedily remove the tumor. A simple imitation of this is a hot poultice of chamomile-

flowers, sprinkled over with a little red wine.

Mr. Ingleby's observations on the great value of active blood-letting in cases of contracted vagina from cicatrices, the results of former injuries, are practical and good; but why is the name of Dewees omitted? an author whose remarks on this subject are of the first-rate merit. Our limits will not permit us to go into the details of this section; we will merely make a short quotation from the author's observations under the head of vaginal tumors; the rest we strongly recommend to the attentive perusal of our readers, especially those who are in actual practice.

"There are two forms of ovarian tumors which obstruct the passage of the child. In the one, a small cyst, in connexion with a very bulky cyst, or else a portion of a large cyst, passes into the recto-vaginal septum, and bulges through the posterior part of the vagina. In the other, and that which occurs by far the most frequently, the whole ovary moderately enlarged prolapses within the septum. The descent is peculiarly liable to happen at two periods; the first near the end of gestation, the second during labour, the prolapsus being promoted by the relaxation of the soft parts." (p. 119). An admirable case, among others, is given by Mr. William Birch, of Barton, where the tumor was punctured. The question of puncturing these tumors is ably discussed by Mr. Ingleby, and well worthy of attention.

We pass on to

SECT. 5.—*On the Laceration of the Uterus and Vagina.*

Among other interesting points, the author notices the fact, that rupture occurs more frequently in multiparæ than in primiparæ—a circumstance which would at the first view be scarcely expected, had it not been fully established by long experience. His observations on the situation and course of the laceration deserve attention. "With a single exception, the cervix uteri has been more or less lacerated in every instance which I have seen, the rent being oblique in its direction, rather than longitudinal, extending to the body and side of the organ. The transverse direction has been erroneously represented as occurring most frequently, but of this I have only seen a single case, the rent being confined to the fundus, and the

result accidental." (p. 185). In case of rupture of the uterus, where the foetus has escaped into the abdominal cavity, and where delivery per vaginam becomes impossible, either from the contracted state of the wound, or the firm closure of the os uteri, the author proposes the important question, whether gastrotomy be justifiable.

We agree with the author in considering gastrotomy less dangerous than the Cæsarean operation; and the success which has lately attended this latter operation would strongly tend to support Mr. Ingleby's views. Ten cases of rupture are recorded, four of which are peculiarly interesting—viz. Nos. 6 and 7 terminated successfully. In No. 9, the uterus was ruptured at the eighth month, by the patient falling upon a step; the child escaped into the abdomen, and she died undelivered. We feel strongly inclined to agree with his opinion, that gastrotomy was indicated.

No. 10 is one of those rare cases where merely the peritoneal covering of the uterus was lacerated. "A great number of lacerations were discovered on the posterior surface of the uterus, the largest being upwards of four inches in length and nearly three in breadth; the flap hanging down, and exposing the fibrous structure."

The 6th Section, "*On Inversion of the Uterus*," is short, but one of much interest. Inversion is a displacement of very rare occurrence, but Mr. Ingleby has nevertheless had the opportunity of observing several cases. We agree with the author in considering that "the case of this displacement implies the existence of softening and enlargement," but we do not understand him when he considers that a portion of the placenta left attached to the uterus will cause its inversion.

The four degrees of inversion which are described by the French authors, are very properly discarded, as useless and unpractical: we regret, however, that he has not mentioned the division commonly followed—viz. into partial and complete. Dewees's excellent observations we could have wished to have seen noticed—White's also.

In a note to page 224, Mr. Ingleby says, "Candour induces me to confess having once excised a polypus for the inverted uterus." We do not make this quotation to show where an error in practice has been made, but to express

our high respect for an author who has had the manliness and honesty to avow openly where he has erred. The careful record of an unsuccessful case, in the hands of an experienced and talented practitioner, is worth a dozen successful ones: it points out the difficulties and dangers which we have to encounter, and, by its instructive example, warns us to avoid them. It is candour of this sort which distinguished the celebrated La Motte, more than a hundred years ago — that “*homo sincerissimus*,” as Haller called him; it is the same honourable feeling which has characterized the inestimable records of our own admirable Smellie. Mr. Ingleby has followed an excellent precedent—would that others did the same!

It is of the greatest importance to reduce an inversion as quickly as possible after its occurrence. When done immediately, the reduction is generally effected with the greatest ease; in proof of which we may mention a case where an intelligent midwife recognized inversion to have taken place, and instantly returned it: after a short time, whether from coughing or some other cause, the fundus was again forced down, and she again succeeded in replacing it. It has, however, been too generally supposed, that, if not seen within two or three hours after the accident, the chances of reposition would be very small. Mr. Ingleby has given an excellent case, where he succeeded in replacing the uterus on the eighth day after labour, at which time the inversion took place, and where the patient appeared moribund. Boyer has recorded two extraordinary cases of inversion, which had resisted all the ordinary means of reduction, and which were accidentally but permanently cured by a sudden and violent fall on the nates. The one occurred to a practitioner named Barre, after lasting fourteen days; the other to Baudelocque, after a period of eight years.

Of the seventh and last Section we must say but little; not from want of interest, but want of room. It is entitled, “*On the Signs and Symptoms of Pregnancy; their obscure and deceptive Characters, their Complication with Disease, and the Signs which denote the Extinction of Life in the Fœtus.*” Sixty pages of valuable matter are here collected, on one of the most important subjects of diagnosis. We cannot agree

with the author, in his note to page 240, in considering the plan of bringing down one foot of the child, in turning, as due to Mr. Radford, of Manchester: this was pointed out more than a century ago, but has not, we think, received the sanction of high obstetric authorities. We ourselves advocated this plan at one time, thinking that as the presentation now bore a greater resemblance to that of the nates, the chances of the child being born alive would be so much greater. Our experience has not confirmed this view: by bringing down only one foot, the hips of the child do not enter the brim of the pelvis so equally and readily; and our practice has been more successful since we have made a point of bringing down both feet: compelling the body of the child to move slowly and gradually through the os externum, has generally ensured a sufficient dilatation of the soft parts for the safe and speedy expulsion of the head. This last Section teems with practical matter, as indeed the whole work does. We take leave of Mr. Ingleby with feelings of high respect for his industry, talents, and great experience: we look upon the work as one of great merit, and cordially recommend it to the attention of the profession.

An Account of the most frequented Watering Places on the Continent, and of the Medicinal Application of their Mineral Springs; with Tables of Analyses, and an Appendix on English Mineral Waters. By EDWIN LEE, Esq., M.R.C.S., &c. &c.

THIS constitutes by far the best account to which the English invalid or physician can turn for information regarding the continental watering places. Sir Francis Head's amusing “*Bubbles from the Brünnen*” has tended to make this kind of narrative more anxiously sought after, although even now the efficacy of mineral springs is much less estimated in this country than it is abroad. Mr. Lee has visited most of the watering places on the Continent, and viewed their several peculiarities with an inquiring and intelligent eye. He remarks upon the vagueness of the general direction so often given to invalids, to try a course of “some of the continental waters,” and the impossibility of rectifying this when abroad, as the practitioners at all and each of the places

which may be visited fail not to laud their own waters as of sovereign efficacy in the particular complaint, be it what it may, under which the applicant happens to labour. Some good illustrations are given, to prove that the benefit so frequently derived from a visit to some favourite spring or bath, is not to be attributed so entirely as many imagine, to the change of scene and recreation attending the employment. And among other arguments used by Mr. Lee, is the occasional instinctive preference for the particular waters displayed by the lower animals. Thus, Alibert says, "It is a known fact that at Vichy, in the month of April, the period when the snow melts on the mountains, when the wind has passed over the springs from the direction of Puy de Dome, and has carried the vapour to distances more or less considerable, the ruminating animals on the left bank of the Allier swim across the river to come and drink with avidity at the springs of the establishment: the waters are then fit for use, and the people of the country are in the habit of saying the season has commenced, the beasts have passed across—*les bêtes ont passés*."

The above anecdote will probably bring to the minds of our readers the legend of Bladud, who was led by his swine to the discovery of the springs at Bath.

Mineral springs owe their impregnation either to fixed or volatile ingredients, and some of the most celebrated yield but a very small portion of solid matter on being subjected to analyses. Thus Wildbad yields only 1 gr. in sixteen ounces of water, Gastein $1\frac{1}{2}$ gr., and Pfeffers $2\frac{1}{4}$ grs., while on the other hand Pullna yields as much as 182 grs., Saydschutz 160 grs., and Seidlitz 126 grs. In some the gaseous parts are merely suspended in the water, and consequently escape very rapidly after it is drawn. This occurs at Hartfell, Cheltenham, and Tunbridge, where, as at Seltzer, Pyrmont, Spa, and some others, the gaseous constituents are intimately blended with the fluid. This accounts for the great difference in the degree to which various waters are affected by exportation.

It is obvious that mineral waters are sometimes of the alterative class. Their action is chiefly evinced by increase of the secretory functions, and it is asserted that more benefit is often derived from them when their effects are insen-

sible at the time. Nay, Dr. Kreyrig informs us that a cure is not unfrequently preceded by augmented indisposition, the excretions being diminished, the face becoming flushed, the pulse strong, and the sleep disturbed. After a fortnight or three weeks, a crisis supervenes, generally in the shape of purging, which is followed by immediate relief.

For the history of particular Springs, we must refer to the work itself, which, embracing an account of the chief watering places, both at home and abroad, will be found a useful manual, either by the physician, or the invalid travelling for his health.

MEDICAL GAZETTE.

Saturday, November 19, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

MEDICAL WITNESSES' BILL.

LEGISLATION EXTRAORDINARY.

THE representative of Finsbury has, ere this, we fancy, found out that it is one thing to push a short bill through its stages so as to have it made a law, and another to make that law work. It may happen that the object of the law is ridiculous and absurd—as when some one got a bill passed to prevent the cry of "sweep:" or the object may be good—yet, through the ignorance of the party that fathers the bill, its provisions may be of such a nature as to be almost impracticable. In either case the measure which may seem to have obtained the sanction of parliament, generally proves abortive, and oftentimes mischievous.

The latter has been the case with Wakley's act, which coroners and overseers either persist in knowing nothing about, or amuse themselves in laughing at: while so far as it has been attempted hitherto to bring it into operation, it has only been productive of annoyance and mischief to the profession.

We had long suspected that this

would be the result: for we never dream of procuring good liquor out of foul vessels. We saw the inconvenience of the patronage obtruded on the profession: and though we acknowledged fully the desirableness of having some legislative protection for medical men in the matter of attending and giving evidence at inquests, we had more than mere misgivings that simple as was that object, it could not be attained under the more than questionable auspices of our *honourable* contemporary.

When the act was passed, however, we were unwilling to mar it by any hostility of ours. Nay, our love of fair dealing induced us to offer the tribute of a compliment to the Finsbury member: for, to do him justice, he worked very assiduously to get the thing shoved through—his only hope—the only little progeny which he could manage to have born alive, after all his legislatorial exertions. The intention seemed good, however ridiculous the means of carrying it into effect. But the rickety brat proves very unmanageable—a nuisance that must be abated: and if some method cannot be speedily devised to counteract its tendency to mischief, a summary step towards its absolute suppression must be adopted.

It is amusing to observe the anxious parent endeavouring to make excuses for the stubbornness of his bantling. Week after week we find him attempting to pacify those who have been deceived and disappointed in their expectations. What a blessing to have a law-maker, and an expounder of the law, in one and the same person!

One complains that he had been cheated into an attendance, and that when, on giving his evidence, he asked for his fee, the Coroner only mocked him: he had not had a *special* summons. This, of course, is not Mr. Wakley's

fault, for the witness should have taken care to have been "*special*ly" summoned,—as if the witness dare be absent on receiving an ordinary summons! Come, come, our *honourable* friend, no mystification! The Coroner, maugre your bill, has just as much power as ever he had, to compel any medical man to attend his court: the new arrangement only giving him and the jury a discretion, when it so pleaseth, to issue a special invitation. But what if he or they won't exercise this discretion? "Why," says the Finsbury legislator (or ought to say, if he would only speak out)—"if they won't, they won't; and I can't compel them." He insinuates, however, that he has a great mind to try and remedy this part of the bill next session, by rendering it imperative on the Coroner to summon medical witnesses *special*ly in every case. No, no, Mr. Wakley, be honest, and confess that you mean no such thing. Let by-gones be by-gones. You were fortunate enough, in getting your bill through, such as it proves to be; and you will never attempt to add a rider to it, or you are a greater fool than we think you. You know that you have no more chance of carrying such a clause in the House of Commons, than you have of being able to set the Thames on fire. Your attempt to control the powers of the Coroner would be as abortive, as when you endeavoured to become a Coroner yourself!

But hear the expounder on another point. The act provides the munificent fee of two guineas for the attendance and trouble of a witness, specially summoned, and who performs a *post-mortem* examination, with or without a chemical analysis of the contents of the stomach. This is expressly so stated in the statute. A witness, however, inquires of the learned legislator—whether, having received two orders from the Coroner, one for simple attendance, and the other for

the performance of a *post-mortem* examination, he could demand three guineas instead of two? Oh! says Mr. Wakley, to be sure you *ought* to receive three, and the Coroner would be "justified" in awarding it to you. "If (says he) a chemical analysis were instituted, and occupied much time, the coroner would be *justified* in making an order for the payment of *three* guineas; although, if the order were resisted, payment of only two guineas could be enforced against the overseers by a court of law!!!"

Here is a precious legislator and expounder of the law for us! The coroner "justified" in sending the medical witness on a fool's errand, to ask for three guineas, when the act only entitles him to two, and even that cannot be obtained without going to law! What a notion the *honourable* member has of justification! but it is well to know what we are to understand when he tells us he conceives himself *justified* in any of his various sayings and doings.

Medical men now begin to feel what they have gained by Wakley's meddling in legislating for them. The act tells them they have a *chance* of a coroner's order, which may or may not chance to be honoured by the overseers. Both coroner and overseers have declined recognizing the act hitherto; and we believe there has been, as yet, not a single instance of a medical witness receiving any remuneration in consequence of the provisions of the measure. Furthermore, the ends of public justice are frustrated; for never have inquests been conducted in so negligent a manner as since the passing of this bungling bill; the coroner and his jury choosing, in many instances, rather to dispense altogether with medical attendance, than to draw orders which they know will be dishonoured. Yet Wakley says they would be "justified" in ordering even beyond the legal claim!

But if such be the fruits of the actual operation of the measure, what blessings are there not in store for all who come within the reach of its influence! "The enactments of the Medical Witnesses' Bill," says the voice from Essex-Street, (where, by the way, is the unfortunate 'Voice from the Commons?'), "have rendered the duties of medical practitioners more arduous and imperative than ever; nor can they now be neglected without exposing to the risk of irretrievable ruin and professional degradation."

Thus, in brief, the matter stands, according to our profound legislator's own showing. *If a medical practitioner, on receiving the coroner's summons, refuse to attend, he will be fined five pounds; if he attend, he will have a chance of an order for two guineas, with a risk of ruin and degradation!*

We subjoin a letter from a respectable correspondent, who gives us his name and address. The hardship of which he complains is much to be deplored; but we see not what remedy he can have in the present wretched state of our medical legislation.

To the Editor of the Medical Gazette.

SIR,—May I request your opinion and advice on the subjoined affair:—

On the 3d of September, about 2 A.M. I was requested to see a man at ———, who had been run over by a stage-coach. When I arrived he was dead: of course an inquest was requisite. On the 5th, the person employed to summon the jury and witnesses called on me, to request my attendance at the inquest the next day; a distance of about four miles from my house. No written summons was given to me. I attended, at much inconvenience, the next day, at 11 A.M., and was examined. The jury having given their verdict, I requested an order from the coroner, on the churchwardens and overseers of the parish, for my fee; which, after considerable hesitation and numerous objections, I obtained. This order was presented to the acting overseer, who refused

to pay it until he had the sanction of the auditor for the Union, adding, that he would submit it to the Board of Guardians in a few days. Yesterday, after two months, on inquiry, he informs me that the Board says it is the first case of the kind which has come before them, that they are not aware of such an act having passed, and must therefore decline paying it. I requested the Coroner's order to be returned to me, which was done. This, in the shortest manner, is the case, and I wish to know whether you think the fact of my not having received a written summons from the Coroner materially affects the case, as I have received the Coroner's order for the fee. If it does not, how can I proceed against these functionaries?

I trust you will pardon my trespassing on you, but I feel with you, sir, that it is highly requisite for every individual in the profession boldly to stand forward in defence of our rights; and I exceedingly admire the zeal and ability with which you have uniformly advocated the interests of the profession.

I am, sir,

Your obedient servant,

CHIRURGUS.

November 10, 1836.

NORTHERN DISPENSARY.

THE LATE RESIGNATIONS.

THE resignations of the medical officers of the Northern Dispensary (namely, of Dr. Roget, the consulting physician, Dr. Stroud and Dr. Theophilus Thompson, the physicians, and of Mr. Bishop, the surgeon of the institution), which, as appears by their advertisements in the newspapers, took place on the 7th instant, will naturally lead the public to inquire into the circumstances which have given rise to this simultaneous movement on their part. The reason they assign is the prevalence of certain abuses in the department of the apothecary to the Dispensary, of so serious a nature as greatly to impede the efficiency, and injure the character, of the institution; and which, in utter disregard of the strong and unanimous remonstrances of all the medical officers, the Committee of Management have persisted in upholding. We have since heard that the complaint originated in the attention of the late apothecary hav-

ing, for some time past, been diverted from medical views by a desire to qualify himself for the Church; and that during his frequent and prolonged absences from the Dispensary in prosecution of that object (absences which were connived at by his friends on the Committee), he left the business of dispensing medicines to the patients to be performed by young men, who either were not properly qualified, or who did not properly execute this duty. Having lately taken holy orders, he has now left the Dispensary; but the Committee have appointed his younger brother in his place, to the exclusion of other candidates of superior qualifications; thus holding forth encouragement, instead of marking their reprobation, of a principle of so injurious a tendency.

It is evident that under this system of mismanagement no medical man, who has any regard to character, could retain, and that none will be willing to accept a trust, which, if exercised under the control of such masters, could never be effectually or honourably discharged.

ADJUDICATION OF THE ANNUAL PRIZES OF THE SOCIETY OF APOTHECARIES.

THE PRIZE QUESTIONS.

TUESDAY last was the day appointed by the Master (Mr. Hingston) and Wardens (Messrs Johnson and Malim) of the Apothecaries' Company, for the adjudication of the prizes of a gold and silver medal, given by the Society annually. The examiner this year was Mr. Ward, of Wellclose Square. The competitors were six in number. The examination was twofold—*viva voce*, and written. The following were the questions put:—

1. What are the special properties of cellular tissue?
2. What are the special properties of woody tissue?
3. In what parts of plants do spiral vessels occur?
4. Mention any families of exogens in which neither spiral vessels nor ducts are found?
5. What are the compound organs of flowering plants?
6. Describe the structure of the exogenous and endogenous stem.

7. Explain Du Petit Thouars' theory on the formation of wood, and shew that it is equally applicable to endogens and exogens.

8. Where are the secretions of exogens chiefly deposited?

9. At what period are the secretions of herbaceous plants in the greatest perfection?

10. What is the nature of stipules?

11. Are there any orders which are distinguished by the form, presence, or absence of them?

12. What are bracts? State their various kinds.

13. Explain the following terms:—Spike, racème, amentum, spadix, corymb, umbel, fascicle, capitulum, panicle, cyme.

14. Give examples of the following kinds of leaves:—The veinless, straight-veined, curve-veined, netted, ribbed, hidden-veined.

15. Are there any orders which are distinguished by the venation of their leaves?

16. State the use of leaves.

17. What functions are performed by the cuticle and stomata, and why are these organs wanting in submerged leaves?

18. Name any closely allied orders which are distinguished by the number of cells in the anther.

19. Describe the structure of the pistil.

20. Give examples in proof of floral organs being derived from modifications of leaves.

21. What are the conditions necessary for the germination of a seed, and the chemical and physical phenomena accompanying that process?

22. Are there any closely allied orders which are distinguished by the milkiness of the sap?

23. Explain Dutrochet's theory of the motions of fluids in plants, and by this theory account for the dispersion of the seeds of *Momordica Elaterium*.

24. The fruit of *Convolvulus*, and *C. major*, has a descending direction, that of *C. sepium* an ascending. How do physiologists account for this?

25. Define the following terms: conicus, conoideus, cylindricus, tubulosus, ovoideus, ovalis, ovatus, filiformis, capillaris, ringens, labiatus, subulatus, acerosus, truncatus, præmorsus.

26. State briefly the artificial system of Linnæus.

27. Give the essential characters of the primary divisions of plants, according to natural affinities.

28. Translate the following passage, and name the author. "Classes, quo magis naturales, eo, cæteris paribus, præstantiores sunt. Affines conveniunt habitu, nascendi modo, proprietatibus, vi-

ribus, usu. Summorum Botanicorum hodiernus labor in his sudat, et desudare decet. Methodus Naturalis hinc ultimus finis Botanices est, et erit."

29. It is said that plants exhibit a corresponding agreement in structure, and medical or chemical properties. Are there any orders which offer no exceptions to this rule?

30. What is the character of *Ranunculaceæ*, and how are they distinguished from *Dilleniaceæ*, *Magnoliaceæ*, *Papaveraceæ*, and *Nympheaceæ*?

31. How are *Proteaceæ* distinguished from the orders to which they are most nearly allied?

32. How are *Lobeliaceæ* distinguished from *Campanulaceæ*, and *Urticaceæ* from *Artocarpeæ*?

Refer to their proper places in the natural system, the following plants.

33. *Raphiolepis Indica*.

34. *Cluytia pulchella*.

35. *Aralia sambucifolia*.

36. *Olea capensis*.

37. A species of *Muraltia*.

38. *Trachymene lanceolata*.

39. *Escallonia rubra*.

40. *Iberis Gibraltica* *.

Each of these questions was valued by a certain number of marks, the total value of the whole series of questions being estimated at 1110 marks. The gentleman (Mr. Jenner) to whom the gold medal was adjudged, obtained 965 marks, while the gainer of the silver medal (Mr. Teggemeir) had 925. The answers of three other candidates were so excellent, that Mr. Ward considered they were entitled to some mark of approbation, but as the meeting on Tuesday was not competent to give this, the motto papers were not then opened, and consequently the names of these three gentlemen are at present unknown. The number of marks gained by the first of the unsuccessful competitors was 885.

Mr. Ward read over to the meeting the answers of several of the candidates to three or four of his questions; and it is but justice to the competitors to say, that they were excellent: and judging from these specimens, we have no hesitation in saying the successful candidates well deserved the prizes they gained.

* These plants were, of course, given to the candidates unnamed.

LECTURES

ON

LOCAL HYSTERICAL AFFECTIONS,

Delivered in the Medical Theatre of St. George's Hospital,

BY SIR B. C. BRODIE, BART. F.R.S.

LECTURE III.

Pathology of Hysteria—Result of Dissections—Treatment of Local Hysteria—Prevention of the Disease—Effect of Tonics—Local applications—Division of Nerves—Other operations—Concluding caution.

ALTHOUGH the examples of local hysterical affections which I have adduced in the two preceding lectures, form only a part of those which you will meet with in practice, they are probably sufficient to answer the purpose of rendering you less liable than you would have been otherwise, to fall into the very common error of confounding cases of this description with those of real local disease. This is the principal object which I have had in view, in directing your attention to this subject: but it is one of much interest, and I am unwilling that you should leave it without proceeding somewhat further in the inquiries to which it leads. In the present lecture, then, I propose to offer some observations on the pathology of these cases, and on the treatment which should be employed for their relief.

Pathology of Hysteria.

Probably the following question has already presented itself to your minds. Is there any sufficient evidence that symptoms so various and dissimilar as some of those which have been described, depend on one and the same cause? Are there good grounds for the hypothesis that a pain in the knee in one case, retention of urine in a second, tympanitis in a third, are only different manifestations of one and the same disease, and that they are connected with the same state of system as that which gives rise to the common fits of hysteria? The same question may arise if you refer to Sydenham's observations on hysteria, in which he has endeavoured to point out the symptoms which may mislead the medical, as I (following him *haud passibus arquis*) have now endeavoured to point out those which may mislead the surgical, practitioner. To this it may be answered, that there is scarcely a single case, such as I have endeavoured to describe, in which, if you have the opportunity of studying its history and progress, you will not find abundant proof of the patient having suffered, in a greater or

less degree, from the ordinary and acknowledged symptoms of hysteria: the two orders of symptoms sometimes existing simultaneously—at other times, and more frequently, alternating with each other; and thus even a limited experience will enable you to satisfy your minds on the subject. But when you have attained an enlarged experience in your profession, you will find that it affords you evidence of another kind, though of such a nature that one individual cannot well communicate it to another, either in a lecture or writing. You will then find, that while no two of these cases are precisely and in all respects alike, it is by no means difficult to trace a series of cases leading from one to the other by an almost imperceptible gradation, and connecting with each other symptoms which, in the first instance, might be regarded as the most distant and heterogencous.

Another question cannot fail to arise in the progress of these investigations. What is the real nature of the disease on which these various and anomalous symptoms depend? We cannot doubt that its locality is in the nervous system. This is sufficiently demonstrated by the characters of the symptoms themselves. Dissection, which illuminates so many of the darkest regions of pathology, affords us little assistance here: at least we derive from it only negative information. I have, in several instances, examined the parts to which hysterical pains had been referred; and in one very aggravated case of the kind, I made a careful dissection of all the nerves by which they were supplied, but I have never been able to discover in them any thing different from what belonged to their natural condition. But every part of the body has its corresponding point in the brain, and the greater number of them have their corresponding points in the spinal cord also. Does the examination of these organs lead to any more satisfactory result? The best proof that it does not do so is furnished by the following circumstance: although so many die of other diseases, who have suffered from hysteria also, and the opportunities of examining the bodies of hysterical patients after death are therefore sufficiently numerous, yet the works of the best morbid anatomists contain no observations whatever on the subject. I have had the opportunity of instituting *post-mortem* examinations in three cases, in which the hysterical affections were of so aggravated a kind as to be, directly or indirectly, the cause of death; and you shall know the result. In one of them, the patient laboured under a very severe hysterical pain in the side, and was liable, among various other hysterical symptoms, to fits, in which

she was scarcely conscious of her own actions. It must have been in one of these attacks that a great number of needles were introduced into one of her legs, which afterwards occasioned much inflammation and effusion of serum into the cellular texture. The patient died, and the body was most carefully examined, but no morbid appearances of any kind could be discovered in it, except what belonged to the œdematous state of the leg. Another case is one to which I have referred already, in which, the patient having long laboured under an hysterical retention of urine, the bladder was found enormously distended, of a black colour, the mucous membrane and muscular tunic being at the same time much attenuated. This patient was an unmarried female, twenty nine years of age. Having been previously indisposed for a considerable time, she was supposed to have sprained her wrist in lifting a heavy saucepan. From this time she was never free from pain, referred to the outer part of the lower extremity of the radius. The pain extended up the fore-arm, and downwards on the side. In November, 1814, about a month after the occurrence of the accident, she was admitted into the hospital. At this time the most careful examination could detect no alteration in the appearance of the limb, but she complained of a constant and intense pain, which extended from the supposed seat of the injury downwards to the fingers, upwards to the shoulder, and again downwards to the spine and sternum. She had great oppression and difficulty of respiration, occasional twitches of the muscles of the face, and any sudden motion of the hand aggravated all these symptoms, and then threw her into a state approaching to that of syncope; in which she was almost unconscious of all that happened, lying with her eyes wide open, and at last recovering with an hysterical sobbing. Her pulse was feeble, beating 120 times in a minute. Forty ounces of urine were drawn off from the bladder, but without any relief as to the other symptoms. The tongue became black and dry; the pulse more feeble; the belly tympanitic; the alvine evacuations being of a dark colour. Then there was hic-cough and vomiting; she became weaker and weaker, and died after the lapse of 14 days from the time of her admission into the hospital. After death, the brain and the thoracic and abdominal viscera were very carefully examined, but no morbid appearances were discovered in any one of them, with the exception of the peculiar condition of the bladder which was described formerly, and two ulcers of the mucous membrane of the *ileum*, each not more than half an inch in length, but oc-

cupying almost the entire circumference of the intestine.

The female, who was the subject of the third case had laboured under a paralytic affection of the lower limbs (*paraplegia*), which Dr. Seymour believed, with good reason, to be connected with, and the consequence of, hysteria. A practitioner whom she consulted, however, thought it advisable to have recourse to repeated blood-letting and other methods of depletion. The result was, the formation of extensive sloughs of the nates and of the soft parts covering the ankles. The patient was now admitted into the hospital, in a state of great exhaustion, and soon afterwards died. The brain and spinal cord were most carefully examined, in the presence of many of you who are now present, but it could not be discovered that they differed, in the smallest degree, from their natural condition; nor were there any signs of disease in the thoracic or abdominal viscera.

In adducing these facts, however, I by no means intend to assert that the organization of the nervous system, in a person who is liable to aggravated hysterical affections, differs in no respect from that of another. The intimate structure of the brain, spinal cord, and nerves, is on too minute a scale for our senses to be able to perceive and comprehend it, and of course there may be differences in the organization of these organs which our senses are incapable of detecting also. There is, it is true, nothing in the history of hysteria to justify the opinion that it is connected with any morbid growth, or morbid change of structure, such as we find to exist in what are usually termed organic diseases: but it is easy to suppose, without reference to organic disease, that the construction of the nervous system, at the period when growth is concluded, may not be the same in all individuals, and that an imperfect development of it may lay the foundation of all the aggravated hysterical affections. It seems to me that this hypothesis affords a reasonable explanation of all the phenomena which those strange diseases present to our observation, and that it is not easy to explain them in any other manner. This being admitted, the connexion of hysteria with the habits of early life, while growth is going on, becomes no mystery. We can understand, also, wherefore it is that the disposition is often, to a certain degree, hereditary—that it prevails in particular families, and that having been once established in the system, it is never totally eradicated. Nor is this opinion in any way contradicted by the circumstance of hysterical symptoms alternating with longer or shorter intervals of perfect health. It is the same with many other

nervous diseases, some of which are much more formidable than these. The lunatic has intervals in which his delusions vanish. A tumor pressing on the brain may occasion epilepsy: the cause exists always, but after the patient has had one fit, weeks or months may elapse before he has another. In like manner a patient may have a nervous system so constructed as to render her liable to attacks of hysteria. While she is strong and healthy in other respects, no hysterical symptoms arise; but if she be weakened by an attack of fever, by loss of blood, by too great exertion of mind and body, or depressed by anxiety, grief, or disappointment, the disease is rendered manifest, and it assumes one form or another, accordingly as accident directs its influence to one or another part of the system.

This view of the origin and nature of hysterical affections derives some confirmation from a circumstance which I have had frequent occasion to observe; although it has not, as far as I know, been noticed by pathological writers. In those who are much disposed to them, there is an evident weakness and laxity of the tissues, independently of what may be supposed to belong to the tissues of the nervous system. Thus there is a peculiar looseness of the joints; sometimes existing to such an extent that they are liable to a kind of subluxation (a slipping in and out, as the patient terms it), without any laceration of the synovial membrane or ligaments. I have known several cases in which a patient, on making some sudden exertion, has experienced a sensation as if some muscular or ligamentous fibres had given way; and, in some instances, a severe nervous pain, referred to this and the neighbouring parts, has remained for a long time afterwards. It is not unusual for the smaller blood-vessels to burst, so as to occasion slight hæmorrhage; although there is no actual disease in the bleeding part. This occurs most frequently with respect to the vessels of the mucous membranes. The disposition to hæmorrhage, however, is not peculiar to these textures. In a patient concerning whom I was consulted with Mr. Mawdsley, there had been repeated hæmorrhages from the ears.

These things must be regarded as indications of want of physical power in the system, and such is the prevailing character of hysterical disease—most distinctly marked, of course, in the most aggravated cases of the kind. A large proportion of hysterical patients suffer from cold hands and feet, have a feeble contracted pulse, a small appetite for food, and are wearied by very small exertions; they are more liable than other persons to lateral cur-

vature of the spine. In some instances, and more especially in the parts which are most exposed to the external temperature, or at the greatest distance from the vital organs, the point of the nose, for example, and the ankles, the circulation is so weak that they assume at times a purple appearance, followed by vesications, and even by a thin slough. These last-mentioned symptoms are, in themselves, a proof of an insufficient generation of nervous energy; they correspond to what is observed after severe injuries of the spinal cord, as well as to what occurred in the following cases, as the consequence of an injury of a nerve. A young man met with an accident, in which the ulnar nerve was divided behind the inner condyle of the arm. The wound healed readily; but when I was consulted, about three months afterwards, the little finger was cold, and deprived of sensation, with purple spots on it, similar to those which precede the formation of vesications. A girl was admitted some years ago into the hospital after a similar accident. The little finger was cold and benumbed, and occasionally the whole of the integuments covering it assumed a dark purple colour: this was always followed by a broad vesication; then by a superficial sore, which, however, healed by the formation of a new cuticle; and this process was repeated several times while the girl remained in the hospital.

Treatment of Local Hysterical Affections.

In some instances the disposition to hysteria manifestly depends on an original mal-construction of the nervous system, which probably has been transmitted from the parent to the child: in others it is equally manifest that it is the result of injudicious management in the early part of life. In the latter order of cases, the ill consequences, which would otherwise ensue, may be altogether averted by the timely adoption of a better system of education; and in the former, much may be done in the interval between the period of infancy and that of growth being completed, to improve the condition of the individual, and to render her situation in after-life less distressing than it would be otherwise.

You can render no more essential service to the more affluent classes of society, than by availing yourselves of every opportunity of explaining to those among them who are parents, how much the ordinary system of education tends to engender the disposition to these diseases among their female children. If you would go further, so as to make them understand in what their error consists—what they ought

to do, and what they ought to leave undone, you need only point out the difference between the plans usually pursued in the bringing up of the two sexes. The boys are sent at an early age to school, where a large portion of their time is passed in taking exercise in the open air; while their sisters are confined to heated rooms, taking little exercise out of doors, and often none at all, except in a carriage. Then, for the most part, the latter spend much more of their time in actual study than the former. The mind is over-educated at the expense of the physical structure, and, after all, with little advantage to the mind itself; for who can doubt that the principal object of this part of education ought to be, not so much to fill the mind with knowledge, as to train it to a right exercise of its intellectual and moral faculties, or that, other things being the same, this is more easily accomplished in those, whose animal functions are preserved in a healthy state, than it is in others?

But these observations relate only to measures of prevention; whereas, in practice, you will have to deal with cases in which the hysterical construction of the nervous system already exists.

The medical treatment of hysteria is in the department of the physician; and as this subject is treated of at length in the lectures on the practice of medicine, I shall only offer a few observations as to the principles in which it should be conducted.

In those in whom the liability to hysterical diseases exists, as I have already had occasion to observe, the symptoms of hysteria are not always present, and much may be done by art towards rendering their occurrence less frequent, and their character less severe, than would be the case otherwise. These symptoms are especially called into existence whenever, from any cause, the bodily powers are reduced below the ordinary standard; and it is reasonable to suppose that an opposite effect will be produced by whatever tends to elevate these powers, and maintain the general health. The whole class of tonic remedies, especially steel, quinine, sulphate of zinc, and ammonia, may, under certain circumstances, be employed with advantage. So also, it is of importance that the patient should live on a generous diet—that she should take exercise out of doors—that she should live in the pure air of the country rather than in that of a crowded city—and that her mind should be agreeably occupied, without being exhausted by great exertions. Nothing tends more to aggravate the disposition to hysteria than the

tedium and *ennui* of a life without occupation; when the mind is, as it were, thrown back upon itself, brooding over imaginary misfortunes, and creating for itself objects of anxiety.

The use of what are usually called anti-spasmodic remedies, especially valerian and assafoetida, is indicated, not where there is merely a liability to hysterical symptoms, but where these symptoms are actually present. Those tonics which are useful in preventing these symptoms, are useful in the removal of them also, especially where the disease assumes a chronic form, as it generally does in the cases which fall under the observation of the surgeon. Here, also, I have in several instances known much advantage to arise from a long-continued course of the sulphate of copper administered in pills, in small doses. Nor must we overlook another important rule of practice. There is often some particular circumstance in the state of the system at the time, which operates as the immediate exciting cause of the hysterical symptoms, and which medicine may remove. For example, in one individual there may be a furred tongue, and a costive state of the bowels; in another deficient menstruation; and purgatives and emmenagogues may be administered with advantage, either separately or in combination. Again, it is not unusual in aggravated cases of hysteria to find the urine depositing a large quantity of lithic acid, in the form of sand; or the urine may be voided high-coloured, depositing a pink amorphous sediment, abounding in the lithate of ammonia; and in either of these cases the exhibition of alkalies, combined with alterative doses of mercury, and a regulated diet, will contribute to produce a cure, the unhealthy quality of the urine seeming to be the cause rather than the effect of the hysterical affection.

On all these points I refer you to the instructions which you will receive from some of your other teachers; but there are some questions connected with the surgical treatment of local hysterical affections, into the consideration of which I shall feel it my duty to enter more fully; although, in so doing, the advice which I shall have to give you will be for the most part of a negative kind, relating not so much to what you ought to do, as to what you ought to leave undone.

Hysterical pains are sometimes relieved by friction with a stimulating liniment—such, for example, as the compound camphor liniment, which may also be used in combination with the tincture of opium. The application of the belladonna plaster is occasionally useful, although it certainly

does not produce those remarkable effects which not unfrequently follow its use in other cases of neuralgia.

Hysterical pains are sometimes palliated by bathing the affected part with the following lotion, applied tepid:—

R. *Misturæ Camphoræ*, ℥iss.; *Spiritus Rosmarini*, ℥iss. M. fiat lotio.

In some instances the patients derive advantage from the exposure of the part to the vapour of hot water. This is especially useful in the cases of that peculiar affection of the wrist and hand which I described in the last lecture.

In those cases in which the limb to which the symptoms are referred is affected alternately with heat and cold, I have known the following plan of treatment to be attended with excellent effects. During what may be termed the hot fit, let a compress be applied wet with a cold spirituous lotion; and when the heat has subsided, and the limb has become cold, let a thick woollen stocking be drawn over it, and then an oiled silk covering over the worsted stocking, so as to confine the heat and perspiration. When the cold fit has subsided, the oiled silk covering may be removed. This local treatment, however, should be combined with the exhibition of the sulphate of quinine, the use of which seems to be especially indicated by the intermitting character of the symptoms.

In some cases of hysterical neuralgia the patient is supposed to derive benefit from the abstraction of blood by leeches, or cupping, or even by venesection. Indeed, I have no doubt that the loss of blood is occasionally followed by a real alleviation of pain. But the relief is never otherwise than temporary; and wherever I have known this kind of treatment to be frequently resorted to, the ultimate result has been, certainly, not only not beneficial, but absolutely injurious to the patient. In fact, we may lay it down as a general rule, that whatever lessens the physical powers tends to prolong the duration of hysterical diseases of all kinds; and nothing produces this effect in a more marked manner than repeated blood-letting. Those who are subjected to this treatment, according to my experience, become almost invariably invalids for life; and I have no doubt that not unfrequently their lives are materially shortened by it.

Blisters, issues, and the whole class of counter-irritants, in the majority of cases increase the patient's sufferings; and there is one objection that may be urged against all local remedies, which applies especially to these, namely, that they prevent the attention being abstracted from the local symptoms. I may take this opportunity

of observing, that nothing is more essential to the patient's recovery than that her mind should not be constantly occupied with the subject of her ailments. The treatment employed should be such as will involve as little as possible deviation from the ordinary habits of life. Thus in a case of hysterical neuralgia of the knee or hip, it seldom happens that any real amendment takes place while the patient remains confined as an invalid to her sofa. The pain may abate, but a sense of weakness follows, which disables her from walking, more than the pain itself, and which, for obvious reasons, goes on increasing in proportion as the confinement is of longer duration. The first step towards a cure is, that the patient should have sufficient strength of mind to begin to use the limb in spite of present suffering.

Another question connected with surgical practice remains to be considered. In hysterical diseases affecting the extremities, will any advantage arise from the division of the nerves which supply the affected part, so as to destroy the communication between it and the sensorium? or from the entire removal of the part itself, by excision or amputation? If the view which I have been led to take of these affections, namely, that they belong to the nervous system generally, and not to the part to which the symptoms are referred, has any foundation in reality, it cannot be expected that such operations will lead to any good result: and the notorious failure of similar operations, when performed in cases of *tic douloureux* of the face, and *tetanus*, undoubtedly tends to confirm this opinion as to their utter inutility. Pathological science, however, is not so far advanced as to authorize us in any instance to disregard the lessons of experience; and it is well, before we arrive at a positive conclusion on the subject, that we should refer to this higher source of instruction.

In a case which I have already mentioned, of a young lady who had a train of most severe hysterical symptoms following the accidental prick of her finger, I was induced (many years ago) to divide the digital nerves. This was effected by a circular incision, carefully performed, extending through the whole of the nerves, integuments, vessels, and cellular texture, to the bones laterally, and to the aponeuroses of the tendons, anteriorly and posteriorly. The result was, that the patient's sufferings were aggravated rather than relieved.

As long ago as the year 1818, I was requested to visit a lady in the country on account of a disease of the knee. I

was led to believe that she had laboured under an inflammation of the synovial membrane, which had in a great degree subsided, but that the harder textures had suffered in consequence, and that the cartilages were in danger of being ulcerated, and I recommended a plan of treatment accordingly. Whether, with my present experience on the subject, I should have taken the same view of her case, I will not undertake to say, but the result was, that a material improvement took place in the first instance. After some time, however, there was a manifest aggravation of all her symptoms. She suffered more than ever; so that she became anxious to undergo the amputation of the limb. I was now again consulted respecting her, but from the written accounts which I received, I concluded that the pain did not indicate the existence of any serious disease, and that the circumstances of the case did not justify so violent a measure as had been proposed. However, her wishes remained unaltered, and two surgeons of eminence in the country yielding to her entreaties, performed the operation. On dissection of the amputated joint, they were surprised to find that there was no collection of matter in its cavity — that the cartilages had disappeared in one spot, of very limited extent — and that there was no other mischief. The stump healed readily enough, but she obtained no relief. I had the opportunity of seeing her some months after the operation, suffering more than ever, with intense pain in the stump, and violent convulsive action of the muscles which move the thigh bone on the pelvis.

Mr. Soden, of Bath, informed me of another of these cases, which fell under his observation, in which also the limb was amputated above the knee, but with no better result than in the case last mentioned. The symptoms attacked the stump, and the patient suffered as much after the operation as she had done before.

The history of a third case of the same kind has been published by Mr. Mayo, in his *Outlines of Pathology*. The knee was amputated, and the stump healed. Soon after, the stump was accidentally struck, and this slight accident was followed by pain in the part, exactly similar to that which had been referred formerly to the knee. Amputation was then performed a second time; but as the wound healed, the pain recurred, being now referred to the stump. Mr. Mayo then divided the sciatic nerve, below the edge of the *glutæus maximus* muscle. At first the pain was supposed to have been relieved, as after the former operations; but it returned on the wound being healed. At this

period I had the opportunity of seeing the patient, the pain which she endured being as severe as ever. In short, she had undergone these various operations, without having derived the smallest advantage from any one of them.

It must be acknowledged that these, and other similar cases which might be enumerated, seem to be quite conclusive against all attempts to relieve these hysterical affections by operation. Some evidence, however, may, and has been, adduced, on the other side of the question.

A young woman was bled in the arm, in July, 1820. The wound healed as usual, but on the 7th of August she was admitted into St. George's hospital labouring under hysterical pain, referred chiefly to the cicatrix, but extending also downwards to the hand, upwards to the axilla, and again downwards on the side to the leg and foot, the latter being at the same time in a great degree benumbed. The whole of the arm was cold, and of a purple colour, and the skin was exquisitely sensible when pinched. On the 25th of August I excised the cicatrix. She was supposed to be immediately relieved, and when the wound made in the operation was healed, she left the hospital as cured. So far, then, it appeared as if the operation had been successful. But observe what happened afterwards. At the expiration of two months, she was re-admitted, not on account of a recurrence of the pain in the arm, but with other symptoms depending on the same state of the general system. The nose was cold, and of a purple colour, and there was a similar condition of the integuments of the ankle. On the latter there was a broad vesication; and both of these parts seemed as if on the point of becoming gangrenous. This result, however, did not take place, and I lost sight of the patient some time afterwards.

In Mr. Mayo's patient*, whose case I have already mentioned, we are informed that he afterwards was induced to perform a further operation—removing the head of the thigh bone from the acetabulum: and I have a letter from Mr. Mayo, in which he states that this last measure has been followed by a relief from pain up to the present time. We are also informed that Sir Astley Cooper† amputated the arm at the shoulder joint, on account of a neuralgic affection of a stump, and that the patient was permanently cured; and that similar operations were performed successfully by Mr. Bransby Cooper and Mr. Langstaff. However, until we know more of these cases than is

* MEDICAL GAZETTE, May 7, 1836.

† Op. cit.

now recorded, it is impossible for us to determine whether they did or did not belong to the class of hysterical affections. Even if they did, the question still remains—how long did the patients remain under the observation of the surgeons afterwards; and was a cure really obtained, or was there simply a commutation of one hysterical affection for another?

In estimating the value, not only of such operations, but of various other modes of treatment which have been supposed at one time or another to be useful in cases of aggravated hysteria, we are never to lose sight of the following circumstances.

1. *Hysterical symptoms frequently disappear at once, without any manifest cause for their disappearance.* Examples of this fact may be found among the cases to which I have had occasion to refer in the preceding lectures. A young lady, who had been for more than two years confined to her bed on account of an hysterical affection simulating disease of the hip joint, recovered suddenly one night while in the act of turning in bed. Another young lady, in whom a long train of most severe hysterical symptoms followed an accidental prick of one of her fingers, after the disease had existed for a great length of time (if I am not much mistaken, for more than two years), recovered suddenly, also. 2. *It still more frequently happens that recovery from hysterical symptoms immediately follows a forcible impression of any kind made on the nervous system.* A young lady, who had long laboured under an hysterical neuralgia of the hip and thigh, and had been unable to walk, or even to stand, in consequence, lost all her symptoms on being thrown from a donkey which she was riding. This case also has been already noticed; and the following are only a few, among many others, which might be adduced, if it were necessary, to illustrate the same principle, shewing that moral and physical impressions are in this respect alike, and capable of producing exactly the same effect.

Many years ago, I attended a young lady on account of a painful affection of the instep, which I certainly did not understand at the time, but of which, with my present experience on these subjects, I am satisfied that it was hysterical neuralgia, and nothing else. She was attended by other surgeons afterwards, who, I believe, were as much perplexed as I was as to the nature of the disease, and who, at all events, gave her no relief. At last, while suffering as much as ever, she was informed of some remarkable cures obtained by the use of the vapour-bath, and champooing, and she immediately went to Brighton, that she might make a

trial of these remedies. The first champooing gave her great relief; the second completed the cure. I was consulted respecting her afterwards, labouring under a nervous affection of the arm and forearm.

I have been informed, on good authority, of the case of a young lady, who had long laboured under a severe hysterical affection, attended with spasmodic contraction of the muscles of one of the lower limbs, and whose symptoms left her suddenly on the extraction of a molar tooth.

In the Christian Observer for November, 1830, we find recorded the history of Miss Fancourt, who had long been confined to her couch, in consequence of what was evidently an hysterical affection simulating disease of the hip joint, and was supposed to have been miraculously cured under the influence of the prayers of her spiritual adviser, leaving her couch at once, and walking down to supper, to the astonishment of her family.

We need not pursue this part of our inquiries further. To you who will soon be engaged in the practice of your profession, what I have now stated will be sufficient to impress your minds with a proper degree of scepticism, and to prevent you being misled by the caprices of these strange disorders. With respect to the great majority of society, who do not know by experience how great is the difficulty of obtaining exact evidence as to the operation even of the remedies in common use, and whose minds are not trained to these investigations, I feel that it would be almost a waste of time to endeavour to enlighten them on the subject. "So ardently," says a distinguished moral philosopher*, "do we desire to find every thing that happens within our observation thus connected with something else, as its cause or occasion, that we are apt to fancy connexions upon the slightest grounds; and this weakness is most remarkable in the ignorant, who know least of the several connexions established in nature. * * * * Many years ago a white ox was brought into the country, of so enormous a size that people came many miles to see him. There happened afterwards an uncommon fatality among women in child-bearing. Two such uncommon events following one another gave a suspicion of their connexion, and occasioned a common opinion among the country people that the white ox was the cause of the fatality." Many of the notions which the public entertain on subjects connected with the healing art, may be traced to the operation of the principle which has been thus ex-

* Reid's Inquiry into the Human Mind; on the Principles of Common Sense. Chap. ii. sect. 9.

posed by Dr. Reid. Conjurors of all kinds, from Prince Hohenlohe and the professors of animal magnetism, down to the most vulgar impostors, will never fail to share the reputation of curing diseases with those who have studied their profession as a science; and it is especially in that class of cases to which I have called your attention in this and the preceding lectures, that their success will be greatest. We must submit to this mortification. But let us at the same time be careful that there is nothing in our own conduct to encourage such delusions. If we would lead the public to more correct views on those subjects, we must first endeavour to make them understand, in some degree, what our art is worth, and what it is not; and, in particular, we must divest ourselves of that morbid anxiety for reputation, which would lead us to claim for ourselves the credit of our patient's recovery, in those instances in which it must be manifest to a disinterested observer that it belongs to the ordinary course of events, to the efforts of the patient's constitution, or to accidental circumstances, and not to our own skill and attention.

Before I quit this subject, I shall trouble you with one further piece of advice. I have told you that it is important that you should not mistake cases of nervous affection for those of real local disease. It is equally important that you should not mistake the latter for the former. Whenever you are in doubt, be careful that you do not employ any kind of treatment which would be injurious if local disease existed. A short delay will always enable you to understand the exact nature of the case, so that you can no longer hesitate as to the remedies which are required for its relief.

BUCKS MEDICAL ASSOCIATION.

DECLARATORY RESOLUTIONS, AND PETITION TO PARLIAMENT.

To the Editor of the Medical Gazette.

SIR,

I HAVE the honour to transmit to you an abstract of the minutes of a late meeting of the Bucks Medical Association, and a copy of a petition to both Houses of Parliament, to be presented early next session, and am, sir,

Your very obedient servant,

ROBT. CEELEY, *Hon. Sec.*

Aylesbury, Nov. 9, 1836.

At a meeting of the Bucks Medical Association, held at the Infirmary in Ayles-

bury, November 3, 1836, Henry Lupton, Esq. in the chair, it was resolved—

That this meeting views, with the deepest concern, the increased oppression and injustice inflicted on the medical profession by the Poor-Law authorities; which, it is to be feared, if passively submitted to, will have a serious influence on its character and station.

That the attempts of the Poor-Law Commissioners to induce the medical officers of parochial unions to fill the subordinate office of district registrars of births, deaths, and marriages, is considered by this meeting to be another device for injuring, insulting, and degrading the general practitioner.

That the recent conduct of the Poor-Law Commissioners and their Secretary, towards Mr. Kingston, of St. Alban's, abundantly manifests their readiness to visit on an individual, *when convenient*, that obloquy and reproach so eminently due to their scheme of medical relief, which, in spite of every remonstrance, they so pertinaciously maintain.

That their professions of humane consideration for the necessities of the suffering poor, and of retributive justice towards those who neglect them, are proved to be insincere, by their allowing the treatment of the sick poor to be let by tender to the lowest bidder; by their forcing medical practitioners, under severe penalties, to undertake duties which, from their nature and extent, are clearly impracticable; by their augmenting the difficulties and increasing the causes of delay in procuring medical aid; and by their utter disregard of the many lamentable and even fatal consequences that have already ensued, and must inevitably recur, from the notorious insufficiency of their *own* arrangements.

That, to secure a judicious distribution, and the proper performance, of medical duties, as well as to furnish a competent tribunal for investigating the conduct of medical officers, it is essential that a medical board, as in the army and navy, should be appointed, to superintend and control the medical department of the poor-law administration.

That a petition, embodying the above sentiments, and praying for inquiry, be presented to both Houses of Parliament, early in the ensuing session.

That this meeting recommends to the notice of the members of the Bucks Medical Association, the circular lately issued by the Provincial Medical Association, for the purpose of collecting opinions as to the mode and amount of medico-parochial remuneration.

That it is highly desirable that medical practitioners should collect and arrange authentic facts relative to their complaints

against the present system of medical relief, preparatory to the proceedings of the expected Parliamentary Committee of Inquiry.

[Then follow two or three resolutions of thanks to individuals, &c.]

The Petition of the undersigned Medical Practitioners, residing in the County of Bucks, humbly sheweth,

That your petitioners deprecate the system of providing medical relief for the sick poor adopted by the Poor-Law Commissioners.

That the prevalence of contract by "tender,"—the general inadequacy of the remuneration—the increased extent of districts, with a diminished and insufficient supply of medical officers—the numerous impediments to an efficient performance of medical duties—and the indignities offered by the new authorities to medical practitioners—are productive of effects equally pernicious to the sick paupers, the medical profession, and the whole community.

That a remuneration calculated to secure proper attendance; a mode of appointment not derogatory to the profession; regulations for the prompt supply of medical relief to the destitute sick; and a general supervision and control of the medical department of the poor-law administration, by a Medical Board, are essential to the interests and welfare of all parties concerned.

Your petitioners, therefore, humbly but earnestly pray, that your Honourable House will speedily take this important matter into serious consideration, by appointing a Committee of Inquiry, and enact such remedies as to your wisdom may seem fit.

And your petitioners, as in duty bound,
&c. &c.

WOUND OF THE BRACHIAL ARTERY,

Cured by Compression.

By J. W. HEUSTIS, M.D., of Mobile.

On the night of the 27th of March, I was called to see a man that had been stabbed in the humerus: as I was not at home, my student, Mr. Carter, attended him, in company with Dr. Lynch H. Deas. We met in consultation a short time afterwards. The hæmorrhage had ceased from syncope and loss of blood, and I found the patient perfectly blanched, and almost lifeless; he was cold and nearly inanimate,

with no perceptible pulse. The wound had been inflicted with a dirk, upon the inner side of the biceps, about six inches below the upper extremity of the humerus. I had previously experienced the efficacy of compression in wounds and aneurisms of the artery at the bend of the arm, of which an account may be found in a preceding number of this journal. It was, therefore, adopted on the present occasion. A graduated compress was employed; and some five or six pieces of money, from the size of a dime to that of twenty-five cents, were wrapped in a rag, and placed accurately on the wound: over this a larger compress was applied, extending five or six inches along the course of the artery, and the whole secured by a roller bandage. A bandage of the same description was next applied, with moderate tightness, from the hand upwards, and the patient left, for the present, to time and repose. The next morning he was better; reaction had taken place, and the pulse in the opposite arm from the one wounded was quite perceptible, although no pulsation could be perceived in the other. On the third day, as he complained of pain from the tightness of the bandage, and as there was some tumefaction of the hand, the compression was slackened, and the pieces of money removed. The arm was still considerably swollen above the bandage, as it had been at first, where the bandage was applied, from the injection of blood between the muscles, and into the subcutaneous cellular substance. The compression, however, had caused this to be principally absorbed, so that where the compress had been applied, there was quite an indentation. The whole of the interior of the arm and forearm were much discoloured with ecchymosis, and tender to the touch.

There was no subsequent disposition to hæmorrhage from the wounded artery, which healed up, together with the external orifice, by the first intention, and without the formation of any aneurismal tumor. The pulse, however, in the radial artery of the injured limb, is still scarcely perceptible, and has probably been rendered impervious at the wounded part. His arm retains its sensibility and motion; the man, however, still remains rather feeble and pallid, from his excessive loss of blood.

From this and other instances which I have witnessed, I am inclined to think that ligatures are seldom necessary in wounds of the arteries of the extremities*.

* American Journal of Medical Sciences, for August 1836.

SIR WILLIAM KNIGHTON.

[We know neither whence, nor from whom, the following has been sent to us; but as it bears internal evidence of fidelity, we give it to our readers just as it has been given to us.—ED. GAZ.]

The Editor of the **MEDICAL GAZETTE** should be informed that the late Sir William Knighton left Tavistock to be with Dr. Geach, who was the surgeon of the Royal Naval Hospital. He was a physician and accoucheur; and as this was before the period of reform, so called, he had a great deal of country practice; and to all his friends he introduced Mr. Knighton, saying, "that he might be trusted as himself, and that he had two advantages of which *he* was deprived, youth and memory." Dr. Geach died suddenly; and although Mr. Knighton's juvenile appearance made some of his patients at first demur, his manner was so prepossessing, that he soon became a general favourite. It was known how assiduously he studied; he was never heard of at a ball or public dinner. In two or three particular cases he met with great success. He attended the daughter of a naval officer, in a dangerous fever, with unwearied assiduity: night after night, for nearly three weeks, he remained by the bed-side. The Admiral's country residence was eight miles from Plymouth. During the day he was spared to see other patients; but at night he returned, when he was anxiously expected. The child's perfect recovery—the parents' gratitude being first due to the blessing of God—was gratefully, and in every respect satisfactorily, acknowledged by them. The mother particularly, to a numerous acquaintance, spoke in raptures of Mr. Knighton: in short, the ladies made him the fashion, and it may be said the lords also; for it was in the time of war, and there were many persons of consequence at Plymouth, in the militia regiments, who had power to patronize him in London. He was exhorted to quit the West of England. He had many friends, who grieved to part with him, but all of judgment felt, that, had it been in their power, they would not have detained him. The difficulty that first attended his practising in London has been detailed; I only trouble you because you passed over in silence the great era which, as I have said, had certainly much influence on the destiny of Sir William Knighton. I do not put any signature, for you know me not, nor do I know to whom I am writing.

Nov. 4, 1836.

PORTRAIT OF SIR B. BRODIE.

To the Editor of the Medical Gazette.

SIR,

PORTRAITS of Sir A. Cooper, Mr. Abernethy, and other individuals of distinguished talents and superior merit, are in the hands of many of us; but, as far as I can learn, a likeness of Sir Benjamin Brodie has never yet appeared. It would give me great pleasure to add my mite to any subscription which might be set on foot to obtain one; and I am only surprised that, considering Sir Benjamin Brodie's exalted station in the profession, and his truly estimable character, this compliment has not yet been paid him.

With many apologies for trespassing on your valuable time, I am, sir,

Your obedient servant,

W. C. W.

London, Nov. 16, 1836.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE IX.

Medico-legal consideration of Impotence in the Female—Imperfect or anomalous structure—Occlusion, constriction, or total absence of essential parts—Sterility, from deficiency of the Uterus—the Ovaries—Modes of ascertaining the fact of Impotence in France, England, Germany—Remarkable cases—Practical suggestions.

HAVING treated, in last lecture, on those conditions, physical and moral, which constitute impotence in the male—and having noticed (always, you will observe, with reference to the requirements of Forensic Medicine) those modifications which are recognized as belonging to sexual inability—we shall now proceed to consider the subject of

IMPOTENCE IN THE FEMALE.

The grounds of any alleged inability in the female to have sexual intercourse must be sought wholly in physical causes.

(a.) *Imperfect Development.*

Age.—As in the male, the effect of either immature or advanced age is such as to prevent the reproductive act in the female. The constriction of the vagina previous to the approach of puberty is usually such as to preclude the introduction of the male organ; and so far there is decided impotence: while, with respect to very aged women, the rigidity of the parts may lead to the same result.

The time at which this incapacity ceases in the young, and begins in the old, is by no means fixed; but we can give a nearer guess at that epoch in the girl than in the old woman. Puberty commences in this country, with females, about the thirteenth or fourteenth year; but it depends greatly on constitutional habit, and modes of education: in other climates it is a good deal earlier, or a good deal later, according to the temperature. On the other hand, it is very uncertain when females cease to have an ability for sexual intercourse: they have continued to be prolific in some cases even to their fiftieth or fifty-fifth year.

(b.) *Anomalous Structure.*

Occlusion.—The most obvious physical cause of impotence in the grown female would be occlusion of the vagina, from whatever cause. There was an ancient practice (and, indeed, travellers inform us it is still observed in some parts of Africa) of preventing young women—slaves, for instance—from having connexion, by artificially producing this impediment. Inflammation, generally by the cautery, was excited in the labia, and the opposite surfaces were thus made to adhere: an operation afterwards being necessary before the generative act could be effected. There is a curious passage in the *Menagiana* on the subject, where it is said that this practice, familiarly termed *boucler les femmes*—is what was really meant by some old authors, who treated *de castrandis mulieribus*. It resembled the infibulation of boys, and perhaps was more properly of that nature, when performed, as it sometimes was, by sutures, or by rings drawn through the parts, still further secured by a lock. I may refer to an erudite note in Beckmann (*Inventions and Discoveries*, vol. iv.) where he treats on this point with his accustomed research, and traces the origin of the lock—the *cademat des jaloux*, which some consider rather as an Italian than a French in-

vention. Brantome says that they were not much employed in France, *because the ladies soon found out how to make false keys*. And Bonneval tells us that, while in Italy, he once met with a lock of this kind, which he had long wished to see.

One remark more may be made on infibulation: it was practised in this country at one time, to prevent cattle from copulation. In Harvey, *De Generatione Animalium*, we have an account of a beautiful mare which was presented to the Queen, and which was infibulated—"ejus genitalia (ne ab equis admissariis inita, corporis gratiam atque equitandi usum amitteret) equisones, ut fieri solet, annulis ferreis infibulaverant;" but she was impregnated, and brought forth young notwithstanding.

But adhesion of the labia, causing at least temporary impotence, may occur in females from accidental inflammation; and such accidents are not uncommon in children. The hymen, also, may be of so tough a consistence as to defy any ordinary means of rupture. In all such cases, however, the assistance of surgery will remove the impediment to sexual intercourse.

Absence of a vagina.—The vagina is sometimes altogether wanting, or in so questionable a state as to preclude sexual intercourse. A remarkable example of this is to be found in a case quoted by Foderé, from the *Causes célèbres*. A female, aged 25, married; but six years passed away, and there was no consummation. It was now deemed necessary that her person should be examined by a midwife, who declared, that instead of external sexual organs, there was nothing to be seen but a solid body pierced by a small hole. It further was ascertained that the woman had never menstruated: but she had always enjoyed good health, notwithstanding. M. Dejours, a surgeon, who was called in, supposing the case to be one of simple occlusion of the vagina, proposed to divide the barrier, in hopes of reaching and laying open the cavity. He accordingly carried a scalpel to the depth of two fingers' breadth, but instead of reaching a vagina, he was still opposed by solid resisting parts. Finding this, he judged that he had nothing to hope for in going further, and that he should run great risk of wounding the bladder or rectum. He therefore contented himself with keeping open the wound by the introduction of tents, and this opening remained during life. Matters remained quiet for eight years, when the husband in disgust demanded a divorce: it was not granted—probably through the reporters holding out hopes of another operation being successful. The woman died at Lyons ten years afterwards, and on examination it was found that the place of the vagina and uterus was occupied by a hard

compact substance, in which no cavity could be traced.

Dr. Beck cites, from the New York Medical and Physical Journal, a recent, and perhaps not less striking, instance of deficiency of the vagina. A woman, aged twenty-three, has been married upwards of two years: she has had excellent health, yet never menstruated. There is, however, about every twenty-eight days, a feeling of uneasiness about the pelvis, followed, for a day or two, by an active diarrhoea; and this she has experienced since the age of seventeen or eighteen. As no sexual intercourse could be effected, she consented to be examined; when it was found, that although the external parts were well formed, there was no vagina. About the usual situation of the hymen, there was found a complete septum. Imagining that this might be an imperforate hymen, Dr. Mott made an incision into it about an inch deep, but without success. He afterwards tried it to the depth of two or three inches; but still no trace of a vagina could be discovered. Dr. Mott suspects that the uterus, as well as the vagina, is wanting. The woman has never had the least sexual desire.

Excessive constriction.—As to extreme narrowness of the vagina, it can in general be scarcely considered as a cause of impotence. Besides that all conditions of largeness and smallness are merely relative, it is certain that art can do a great deal in remedying the inconvenience.

Benevoli was called upon to treat a married woman whose vagina had no larger calibre than that of a goose-quill. Every effort to dilate the part seemed fruitless. The parietes of the passage were of a scirrhus hardness. A divorce was about to be sued for; but the surgeon, by the employment of emollient fomentations, and the successive introduction of pessaries of gentian root (gradually enlarged), succeeded in ultimately rendering the part of the usual size.

There are, however, certain cases, it is said, in which, owing to excessive constriction and thickening of the parts, coition is totally precluded.

Yet it would appear, that even in the most unpromising cases of this kind, the natural powers, unassisted by art, may sometimes prove effectual in restoring the proper conformation. In the Memoirs of the Academy of Sciences of Paris, there is a case which confirms this view. A young woman, who married at sixteen, had the vagina so narrow as scarcely to admit the introduction of a common quill. At every successive menstrual period she experienced a painful tension of the womb; the catamenia flowed with difficulty; and

it was supposed that the upper part of the canal was still more constricted than the lower. Sexual intercourse seemed perfectly impracticable: yet, after being married eleven years, she proved with child, although the vagina still preserved its strait condition. That she could ever be delivered seemed now scarcely possible. Towards the fifth month of pregnancy, however, the passage began to dilate, and by the ninth it was of dimensions sufficient to allow the safe birth of the infant.

Irritability. — Excessive irritability of the sexual organs, attended with intolerable pain when coition is attempted, must be considered as in some measure a source of impotence, which it may be very difficult to remedy. Dr. Cockburn traced a case of this kind to internal hæmorrhoids, and removed the effect together with the cause. Mr. White is quoted by Dr. Paris, as having published three very interesting cases, in which the pain which accompanied the attempt at coitus was so acute, that the women rarely escaped fainting. Upon examination, the surgeon discovered in each of them a small fistulous opening, leading into a sinus of at least two inches and a half in length. The disease was attributed in each instance to a local injury having some years previously occasioned an abscess in those parts. This painful state of the vagina was entirely and permanently cured by dividing the sinus.

Total absence of external organs. — But where the external organs and the vagina are wholly wanting, there can be no hesitation in pronouncing for both impotence and sterility; unless, indeed, the latter passage have an opening somewhere else, as on the abdomen—at the navel, for example; or unless it communicate with the rectum. In either case it is possible—indeed it has happened—that women have conceived: and the question has even been proposed to the casuists, “whether, if a wife be so formed, it be lawful to have connexion with her?” Much heat and contrariety of opinion were displayed on this point, and a judicial decision in the negative was pronounced by a royal court of justice, at Treves. However, I shall quote for you a remarkable case or two.

M. Barbant, in his Midwifery, relates that in two cases of communication of the vagina with the rectum, delivery was effected—once by a laceration which extended to the meatus urinarius; and in the other instance by an incision, which was requisite for the removal of the fœtus.

A young woman of Piedmont, who had no external genital organs, got married; but as her malformation was known, it was not suspected that pregnancy could

possibly take place; and, consequently, some labour pains of which she complained were imputed to colic. Upon examination it was ascertained that there was *no trace* of the external organs of generation. It was thought that the pains were from retention of the menses. Professor Rossi (who relates the case) examined the rectum, and determined to make an incision in the natural direction of the vagina. He was much astonished on feeling with his finger, which he introduced into the wound, the membranous sac containing the waters lying over the opening of the neck of the uterus. The membranes at length gave way, the head of the child presented, and the labour was completed by the natural efforts. The new passage was kept open by means of a tube, distended with air after its introduction, so that the artificial vagina might be of the natural dimensions. Two years afterwards this female proved pregnant again, and was delivered by the new opening. The information gained from her husband led to a more careful examination of the rectum, and an orifice was found within the anus, which would only admit a small probe. This orifice communicated with the artificial canal made by the surgeon; and there could be no doubt that it was through it that the first impregnation had been effected. It is further worth observing, that the orifice did not pass in the direction of the opening of the cervix uteri, but formed an angle with the part*.

Absence of the Uterus. — The uterus may be absent: this is one of the physical causes of sterility, and perhaps the only one, which can be ascertained by actual examination; the vagina in such cases being a mere *cul de sac*.

There is a case related in Hufeland's journal, where Professor Stein, in proceeding to remedy what was supposed to be merely a constriction of the vagina, ascertained to a high degree of probability that there was no uterus present: the vagina terminated in a mass of cellular tissue. Dr. Stein quotes several instances of the same anomaly, which he found already on record.

In a female operated upon by Dr. Macfarlane, of Glasgow, for what appeared to be imperforate vagina, the thick muscular substance which formed the occlusion was divided, but without effect. The patient died, and it was ascertained that she had no uterus; but the ovaries were large and well formed, and the breasts fully developed.

It was Van Helmont's opinion that womanhood essentially depended on the womb—*propter uterum solum mulier est id*

quod est ; but the last case, as well as several others which might be quoted, shews that the external appearance and attributes of the sex cannot depend on that organ, but on some other, which is invariably present when a woman exhibits the sexual characteristics of voice, shape, habits, propensities, &c. Such an organ is the ovary, which bears an exact analogy in this respect with the testicle in the male.

Deficiency of the Ovaries.—Some remarkable instances are on record of one or both ovaries being wanting in females examined after death; but perhaps the most curious example of their absence is that related in the Philosophical Transactions for 1805, by Mr. Charles Pears. The woman in question lived to be 29 years of age, but had not grown after ten. She was only four feet ten inches in height, and had a very narrow pelvis as compared with the breadth of the shoulders. Her breasts and nipples never enlarged; nor did she ever menstruate, or shew any other sign of puberty, physical or moral. She died of chest disease. On examination after death, the uterus was found to be in every respect natural, save that its size shewed it had not enlarged beyond the infant condition. The fallopian tubes were pervious throughout; but the ovaries were so indistinct, that they “shewed rather the rudiments which ought to have formed them, than any part of their natural structure.”

When the ovaries are deficient, we can very well conceive that they may entail impotence as well as sterility. In fact, persons in this condition are similarly circumstanced with eunuchs; for while the latter lose their sexual character and appetite, as well as power for intercourse, the former also are unsexed, and destitute of all reciprocal feeling. The woman just described by Mr. Pears “always expressed aversion to the familiarities of young men.”

The difficulty respecting the ovaries in a medico-legal point of view is in making the diagnosis; for however we may ascertain in the living person the presence or absence of an uterus, we can scarcely hope to demonstrate the fact with regard to the ovaries, and can be guided by circumstances alone. It may happen that, in addition to the unfeminine characteristics of the individual, we may obtain cognizance of some disease of the abdomen under which she may have laboured, or of some accident which might have destroyed the vitality of one or other of the ovaries. Zacchia thinks that the loss of one ovary is enough to render a woman sterile, and that a female in such a condition is even worse off in respect to reproduction than a spado, who has only one testis.

In the passage where he expresses this opinion, Zacchia, by the way, speaks familiarly of the castration of females. He had mentioned just before, that it was an ancient practice in use among the people of Asia Minor, and, as he understood, prevailed in his day in some part of Germany. It is probable that, with respect to the latter circumstance, the shrewd old jurist was misinformed, and that the Asiatic practice was no other than that already alluded to, as consisting in producing occlusion of the vagina.

But there can be little doubt, indeed it is certain in some cases, that the ovaries have been actually removed. Mr. Pott removed them in operating for inguinal hernia, and a complete change came over the female so deprived. Before this period she was stout, large-breasted, and menstruated regularly; afterwards, although she enjoyed good health, she became thinner, her breasts were gone, and she never menstruated. Her age at the time of the operation was 23. De Graaf, referred to by Mahon (though I have not been able to find the passage in the treatise, *De Mulierum Organis*), mentions a German who cut both the ovaries out of his daughter, being provoked at her misconduct, and wishing to render her more chaste: and Boerhaave (quoted by Dr. Paris) relates the story of a sow-gelder in Spain, who, in a fit of passion, treated his daughter in the same cruel manner. In both instances the women seem to have escaped with life, but their sexual characters, it is said, were completely destroyed.

Other supposed causes.—Other reputed causes of impotence and sterility in women—such as prolapsus of the uterus, or of the vagina—need not delay us; they are so reputed without any sufficiently good reason: conception has been known to take place in such conditions of the female, as well as when fluor albus, immoderate menstruation, or even a carcinomatous state of the womb is present.

I have omitted for obvious reasons many of those organic causes of impotence and sterility, in both male and female, which are wholly internal, for they afford no indications to the medico-legal practitioner. They are in general not ascertainable until after the death of the individual, and mere suspicions in a case of this nature can be attended with but little practical utility.

Means of determining the question of Impotence.

The earliest provision met with for dissolving a marriage by reason of impotence, is in Justinian's code; where it is stated, that if the parties have lived

two years together without consummation, —*si maritus coire minime propter naturalem imbecilitatem valet*—a divorce is to be granted. In a subsequent law, the time is extended to three years. But in what manner the old civilians satisfied themselves of the husband's incapacity appeareth not. It was the Canon law which introduced the mode of proof by personal inspection. The husband was inspected first, and if he appeared capable, the examination went no further: the woman (the complainant) was obliged to be silent. But if, upon inspection of the husband, there were doubts raised as to his ability, the wife was then inspected, provided she had not been married before. This method of inspection, too, was adopted by the Canonists as a sort of *dernier ressort*; for, in ordinary cases, the affirmation of the parties, with that of seven of their relations, was held sufficient.

The Congrès.—It remained for France to introduce the most disgusting and absurd mode of proof ever devised. This was the actual congress, which was commonly had recourse to for about a century and a half, but was at last abolished by a special law, in the year 1677. It is said that the number of divorces sued for and granted within this period, was greater than was ever before known. Women who wished to be divorced, and were aware of some apparent deficiency or diffidence in their partners, had only to challenge to the congress, and all the chances of victory were in their favour. There was one remarkable case, however, in which the lady was defeated. The circumstances of this case are illustrative of some points in the present lecture, and therefore may be, perhaps, not inappropriately introduced. The Baron d'Argenton was accused of impotence by his wife, in the year 1600: she had actually gained her cause before the Official of Sens, and afterwards before the delegates of the Primacy of Lyons. The Baron appealed from the sentence; he maintained that he had consummated the marriage, demanded that his wife might be inspected, and finally offered to accept the congress. Rouillard, his counsel, one of the most learned advocates of the parliament of Paris, published a capitulary on the occasion, proving "that a man born without any visible testicles, but having all the other marks of virility, is capable of the conjugal duties." This was the Baron's case. The tables were turned on the lady, who now declined either a congress or an inspection, as being equally repugnant to her modesty. It is scarcely necessary to add that she lost her cause. The able advocacy of Sebastian Rouillard, upon this

occasion, was rendered memorable by the strong arguments adduced in favour of the congress; they were full of ingenuity, and deservedly admired for their wit and learning. But a greater advocate arose a few years after, in the person of Vincent Tagereau, who demonstrated in a very eloquent tract, (*On the Impotence of Men and Women*) that the method of proof by congress was both immodest and uncertain. Paré also wrote against the practice, and called loudly for its suppression. Nor was there, perhaps, a more efficient champion on the side of modesty than Nicholas Venette, a learned physician of Rochelle, whose work, entitled *Tableau de L'Amour Conjugal*, went through several editions. He denounced the *congrès* as "a pretence for a divorce, and the effect of the lasciviousness and impudence of women. They induce the judges to grant a trial, which is as precarious as it is indecent: for not one man in a thousand can come off successful from so public an ordeal."

The proceedings of the congress are variously described; some say that they were conducted with circumstances of disgusting indecency, under the immediate eye of the inspectors, (namely, the physicians, surgeons, and midwives, three of each, besides a magistrate); while others assert that the midwives alone were in immediate attendance, the professional men not being summoned until the moment sufficient proof was producible. Voltaire distinctly denies that there was any very indecent ceremony observed. "This proof," says he, "about which so much noise has been made, was not conducted exactly as people have imagined. It has been supposed that a conjugal consummation took place under the inspection of witnesses; but such was not the fact. The parties simply retired to bed, and at a proper time the inspectors, who were assembled in the next room, were called on to pronounce upon the case."

However this be, the *congrès* continued for half a century after the remonstrances of Paré, Tagereau, and others, and would probably have been retained longer by the law authorities, had they not been made ashamed of their conduct in a memorable case. The Marquis de Langeais, in 1659, was accused by his wife of impotence, and having accepted the congress, *failed*, as it is said, through the management of the lady. He demanded a second trial, but the judges refused, pronounced the Marquis impotent, his marriage void, forbade him to marry again, and allowed his wife to take another husband. The Marquis, however, disregarded one part of the sen-

tence; he married a Mdlle. de Navailles, and had by her seven children. His first wife having died, he appealed to the Grand Chamberlain against the sentence of impotency; whereupon this great officer, sensible of the ridicule of the whole affair, confirmed the second marriage, admitted the appellant's ability, and procured a law whereby the ceremony of the congress was ever after abolished.

The French law at present seems to have run into the other extreme: it is totally silent on the subject of impotence, obviously with a view to discountenance such a charge as a ground of divorce.

Mode of investigation in England.—Not so, as we have seen, in England; here impotency and sterility have long been admitted as sufficient grounds in nullity of marriage; and impotence, as we have further seen, is recognized by our ecclesiastical authorities, according as it is absolute or relative. The case of Lord and Lady Essex has been already alluded to; but the steps which were taken for the dissolution of their marriage are further deserving of notice. It was notoriously the wish of the lady to be divorced, in order to be married to her paramour, Viscount Rochester, the King's favourite. For this purpose she trumped up a charge of impotence against her husband, and so managed matters that he was effectually so in respect to her, and had no hesitation in confessing it, as he was anxious to get rid of a woman so worthless.

It was resolved, therefore, to proceed in accordance with the established practice. The parties had been married above three years, and the wife pleaded, that although she was *apta viro*, she was notwithstanding a *virgo intacta*; in proof whereof, she offered to submit to the requisite personal inspection. How the remainder of the proceedings were conducted I shall relate in the words of a writer of the period, merely observing, that there is no reason to believe that there is any exaggeration in what is asserted of the device adopted by the Countess. The partiality of the King was notorious throughout the whole affair; and the eagerness which he displayed in bringing about this adulterous union, which afterwards led to the murder of Sir Thomas Overbury, has left an indelible spot on his reign.

"The King commanded the bishops to sue out a divorce between the Earl and his lady, in order that the Viscount might marry her; for he had been practised formerly in Scotland, in his minority, with the like experiment. Elizabeth, daughter to the Earl of Athol, being married to the Earl of March, under the pretence of impotency, but merely for lust (as the author

reports), was divorced from her husband, and married to the Earl of Arran, the King's favourite, who had been before a partner in her adultery.

"The bishops and others, having a commission under the great seal to convene the Earl of Essex and his Countess before them, sent out their summons, and they made their appearance accordingly. But before they proceeded, they caused a jury of twelve discreet matrons to be impanelled, to search the Countess, whether she were (as she pretended to be, and was reputed) a maid still; for if she were a maid, they would fasten upon a nullity, and so separate them for the more honour of her virginity. The Countess being ashamed [or afraid] to come to such a trial, would not expose her face to the light; but being to appear before the matrons, under a veil, another young gentlewoman, who had less offended, was fobbed into her place; and she passed in the opinion both of jury and judges to be a virgin. Then the articles were drawn up, where she accused her husband of impotency, whereby, &c. The good Earl, willing to be rid of so horrid a mischief, made an acknowledgment, upon which the judges proceeded to a divorce."

The custom in this country, in trying the incapacity of women, as well as of ascertaining whether they be, as they state, *intactæ*, still is, to submit them to the scrutiny of a jury of matrons.

The reputed impotence of men is generally referred to the investigation of inspectors chosen by the court, and duly sworn: these inspectors are generally two surgeons and two physicians; and such a jury has in several instances latterly been substituted for the absurd and ignorant jury of matrons.

German proceedings.—In Germany the usual method is to commit the investigation of the proofs to the recognized medical inspectors, generally an *Amt-Physikus* and *Amt-Chirurgus*, who draw up their report, and present it for adoption to the higher authorities. I have before me two of these reports, recently published by Professor Bernt, in his *Gerichtlich-Medicinische Gutachten*; but the extreme indelicacy of both forbids me to give more than the briefest sketch of their details.

In the first case, a man aged 48, being charged with impotence by his wife, a young woman of 18, the parties appear in person to be examined. The man has been already divorced from a former wife for inability; and his general appearance is unfavourable: short stunted growth; thin beard; high-toned voice; meagre shapeless limbs, &c. The sexual parts without being malformed, are excessively

diminutive—not larger, in fact, than those of a boy of twelve: the measurements I omit. This person states that he has strong impulses occasionally, and can perform his conjugal duties well enough; that his wife is only prompted to proceed against him by some malicious people, but he hopes to please and to satisfy her yet, &c. On examining the wife the next day, she proves to be a bouncing vigorous young woman, well formed in every respect, and exhibiting no marked appearance of having cohabited: no hymen, however, nor carunculæ. The moral circumstances I forbear to enter upon. In fine, the examiners conclude that the parties are wholly unsuited to each other; that the young woman seems well adapted for having a family, but it is physically impossible (which, by the way, appears to be a little too strong) that the man can ever prove prolific.

The second case is one in which impotence was falsely imputed. The parties were married but a few days when the wife chose to decamp. The husband was thirty-one years of age, underwent the most minute examination of the inspectors, and was pronounced to be perfectly potent. Some of the interrogatories put to the husband by the Consistory Court of Weimar, in consequence of the depositions of the wife, are curious; nor are the replies less so. But I cannot venture to notice them further.

Practical rules.—In proceeding to examine alleged cases of impotence, it may be as well to observe a few plain rules, which may be useful to us, and expedite our researches.

1. We should note the age of the parties, and particularly of the individual complained of. The general appearance, the habit of body, and state of health, should be observed. And we should ascertain what diseases the person may have previously laboured under.

2. The sexual parts must be carefully examined with regard to mal-formed, deficient, or redundant structure. The urethra of the male should be sounded, and the condition of the prostate explored.

3. All manipulations of a gross or indelicate kind should be carefully avoided: they are wholly unnecessary, when there is sufficient opportunity for other examination. It can scarcely be mentioned without disgust, that it is the custom in some of the German states—Witttemberg, for example—to require the professional inspector to lie for some nights in the same chamber with the suspected party, in order to ascertain, by immediate and ocular evidence, whether there be occasional erections! Yet Henke thinks well of this practice.

4. No artificial stimulus should be employed. It is a strange proceeding, and surely very reprehensible, for certain medical jurists to recommend the use of provocatives, by way of giving the accused a full and sufficient trial. Even Haller himself suggested that tincture of cantharides should be administered; and others have prescribed the cold bath, warm vapour, electricity, and *nettes*.

Lastly, Physical causes are those which we should chiefly endeavour to ascertain; and those of an enduring character more particularly deserve our best attention.

The main question, be it constantly kept in mind, is, whether the party be *actually* impotent, and *how long*? For, as I mentioned before, if it be sought to procure a divorce, the bodily infirmity complained of must have existed *previous* to the marriage contract: if it originated *after* marriage, it is no ground of divorce or separation, for the end of the contract may have been answered—namely, the procreation of children.

ERRATUM.—In last lecture, p. 263, last line but three, for “unlawful,” read “lawful.”

DETERMINATION OF THE QUESTION, WHICH ARE THE NERVES OF TASTE?

By B. ALCOCK, M.B*.

My attention having been particularly directed to the physiology of the fifth nerve, the uncertainty in which the relations of the sense of taste have remained, even to the present time, has led me into a series of investigations, the results of which, I hope, will be considered worthy of being submitted to the profession.

The first question relating to the sense which engaged my attention, was the determination of the doctrine of Panizza, that the glosso-pharyngeal nerves are the special nerves of taste.

The name of Panizza is so eminent, and his statement so circumstantial, and stamped with candour, that one must hesitate to call his opinion into question: however, it is so opposed to received doctrines that I determined to repeat the experiments upon which it has been founded.

The following are the results which I have obtained from the division of the lingual branches of the fifth, and of the glosso-pharyngeals; 1st, after the section

* From a paper read at the Bristol Meeting of the British Association, August, 1836; here condensed from the Dublin Journal of Medical Science, for November.

of the former, the animal lost the tactile sensibility of the tongue, and retained the sense of taste; but, though it tasted, it appeared evidently to be by other parts of the mouth, and it seemed equally plain that it had lost the sense in the anterior part of the tongue, at least; for after it had been trained to suffer its mouth to be opened, quietly, and to have something laid upon its tongue, it allowed the pure *coloquintida*, moistened, to remain so long upon that part of it, care being taken to confine it to it, that no doubt could remain that the animal did not taste by the organ at its anterior part; but as soon as it was let go and closed its mouth, it displayed at once its sense of the taste by the ordinary indications. The inference therefore of Panizza, that taste continues *unimpaired* in the tongue after the section of the lingual branches of the fifth, is in my opinion incorrect; so far at least as it is understood in an unqualified sense, and its application extended to all parts of the organ. 2nd. I have divided both glosso-pharyngeals in several dogs, with the following results: in two of them, each time that either nerve was taken upon a hook, preparatory to its division, a most violent action of the pharyngeal muscles was excited, resembling precisely the pharyngeal effort to reject the matter, which most persons must have experienced, when something nauseous or revolting has got beyond the power of the tongue, and entered the pharynx; and it was so imperative, that the animal struggled to get upon its feet, and was with difficulty restrained. In a third, a similar effect, only less marked in degree, was produced, by pulling upon the nerve with a ligature passed underneath it; and in one of the three the root of the tongue was at the same time depressed, and rendered concave from side to side. In three of the animals, muscular startings occurred in the throat, while the nerve was held upon the hook; but the phenomenon just described did not, at that time, take place. In one of those the startings were strong and repeated; in the others, though obvious, they were less remarkable; and in one also, as has been mentioned, the first effect described was caused by pulling upon the nerve. In all but one, the animal displayed much suffering from stretching, pinching, and division of the nerve. In every instance deglutition was more or less impaired; I say more or less, because in my first attempts I did not succeed perfectly in dividing the nerve, but only its pharyngeal division; and this occurred in the animal which I presented to the Surgical Society of Ireland, during the past session; as I afterward learned from dissection: in that instance the animal

required at times repeated efforts in order to get a morsel down; though at others it appeared to swallow with tolerable freedom. But in those instances in which the nerves were perfectly divided, deglutition was so very much interfered with, as in some cases to be impossible: the animal took, and masticated the morsel as usual, and swallowed it from the mouth into the pharynx freely; but then, after repeated and unavailing efforts to get it further, it made equal efforts to get it back again, in which it often experienced so much difficulty, as to become much exhausted, or to seem even in danger of suffocation, before it succeeded. Yet even here the animals, under certain circumstances, were able to get food down—meat in small bits and moist—but if either in large bits or dry, it would not pass. Panizza's conclusion, therefore, with regard to the influence of the nerve upon deglutition, as also that with regard to its sensibility, appears to me as incorrect as the former.

The power of the animal still to swallow, may be readily explained by reference to the mechanism of deglutition; which process consists not of a single act, but is accomplished by a succession of actions in the several successive portions of the part of the intestinal tract engaged in it: hence, where no difficulty exists, the loss of action in one part, the pharynx, may be compensated by the action of the part immediately behind it—the mouth—which may suffice to propel a morsel through the former into the *oesophagus*, and this effect will be favoured by the natural tendency of the matter to descend; but where, from any cause, the pharynx is called on itself to act, then difficulty arises.

Lastly, the animal's taste did not appear, to say the least, much affected: even immediately after the operation, when exhaustion renders it in general very indifferent, it unquestionably tasted the *coloquintida* introduced into its mouth,—in one to such a degree, that efforts to vomit were excited by it,—and when food embittered with it was offered to the animal, it rejected it, though it appeared to me to manifest less aversion than previously. In those experiments, as much as could be of the nerve was in each removed, to provide against reunion. The inference from them, as regards taste, is obvious; that the glosso-pharyngeal nerves, if connected at all with the sense, are not the sole or special media of its perception.

How, then, are the results of Panizza's experiments to be explained? This task belongs properly to another; but justice to my own induces me to suggest two sources of fallacy, by which he may have been misled. I cannot, in the first place,

believe that he operated on the glosso-pharyngeal nerve; and failed to find it sensitive, or to influence muscular action; yet he asserts that it is devoid of both properties; or that he divided the nerve completely, and that afterwards deglutition was perfect. Indeed, from my own experience of the operation, I should say that no one, who makes the experiment once only, or for the first time, is likely to succeed in his purpose, inasmuch as the lingual division of the nerve is so close to the base of the cranium, is so short, and runs so directly inward away from the pharyngeal, that it is almost certain to be overlooked, until, after having, as he thought, cut the nerve at its exit, the operator finds on dissection *post mortem* that he has left the lingual portion untouched; and from a comparison of my experience with the history of the operation given by Panizza, I can hardly hesitate to assert that he did not reach that portion; else he would not have omitted to mention a source of failure the most remarkable in the case: again, he makes no reference to the external carotid artery, which is situate between the surface and the track of the nerve, and which it is, in my opinion, necessary to tie with a double ligature, divide and displace, in order to allow sufficient room, and to guard against hæmorrhage. If not the glosso-pharyngeal, then, what other nerve could it have been? It might be the superior laryngeal: indeed, this nerve is situate so near to the other, that it has very frequently presented in the course of my operations; and I have been for some time uncertain which of the two it was: it is doubtless somewhat lower and somewhat more superficial than the glosso-pharyngeal; but it will be readily understood, that with a deep wound, and a trying operation, the difference in both respects might be easily overlooked. Again, I have not found, in the trials I have made, the superior laryngeal display either of the disputed properties; and, if this conjecture be correct, we can explain how he may have divided, as he thought, the former nerve; and found it devoid both of sensibility and of muscular influence. In the second, beside the acknowledged power of hunger, I have found that some dogs are naturally so devoid of taste, that a conclusion could not be safely drawn with regard to that sense, from the result of any experiment upon them; and I have actually rejected a dog as an unfit subject on that account: the animal ate, uninjured, with avidity, food, which others, naturally voracious, rejected with disgust: and taste might have easily seemed obliterated in it after the division of the glosso-pharyngeals.

It being then, as it appears to me, satisfactorily proved by the preceding details, that the glosso-pharyngeal nerves are not the special media of taste, we are thrown back again upon the fifth nerves, to which it has been generally attributed. But if *they* be the media, with which of their branches is it associated? or, is it restricted to particular branches? The linguals are those which have been generally considered the nerves of the sense; whence they have obtained the name of "gustatory." Several considerations, however, cast a doubt upon that opinion: first, if they be nerves of taste, they certainly are not the sole; since it continues after their division; and secondly, if taste be a faculty derived from them, it might be expected that all parts of the mouth supplied by them should possess it; but they give filaments to parts which are not seats of taste, and thus, while they are proved by the first not to be the sole, the second throws a doubt upon their being nerves of taste at all. Again, in the section of the lingual branch of the fifth, that of the chorda tympani is necessarily involved, and the effect consequent on the division of the former may be due to that of the latter; while it is one of a set, and the only set, of nerves distributed from a common source to the seats of taste in the human subject, viz. the branches of the spheno-palatine ganglion. Those considerations—to which is to be added that suggested by Mr. Noble, that no other function has been with any degree of certainty assigned to the cord—appeared to me so forcible as to induce me to adopt the opinion, that the ganglion and its branches are the source and media of taste to the tongue and fauces, the seats of the sense in the human subject at least. The same opinion has been already suggested by Mr. Noble of Manchester, and advocated by him on rational grounds. Bellingeri also maintains the doctrine that the chorda tympani is the source of taste; and it appears further to have been adopted by Magendie; inasmuch as we have been lately informed of his removing a defect of taste by passing a galvanic current through the course of the cord. To the doctrine two objections, however, present themselves: viz. that the branches of the spheno-palatine ganglion are distributed to other parts beside the seats of taste—the nose—and that even its palatine branches cannot all be considered nerves of the sense, since we do not taste with the hard palate; and hence either taste is not a special sensation, or those are not its special nerves. On the other hand, those objections might be removed by the principle, too much disregarded in our reasonings upon the source of sense, that

peculiarity of sense may be equally, or even more, the result of peculiarity of organization in the organ, as of peculiar nerves; and experiment alone offered a prospect of solving the difficulty.

But how experiment upon the sphenopalatine ganglion and its branches? Notwithstanding the apparent impracticability of it, it occurred to me to attempt the removal of the ganglion from the dog, and thus directly decide the question. In this design I was encountered at the outset by the authority of Magendie and Desmoulins, according to whom neither ganglion nor chorda tympani exist in that animal. On dissection, however, I ascertained with great facility that both do exist, and not only in the dog, but also in every one of the individual mammalia from which they expressly state that the parts are absent. Further, I learned that the dog presents a most felicitous opportunity for determining not only the influence of the ganglion upon taste, but also its relation to the fifth nerve. In the human subject, the ganglion exists upon a branch of the nerve; and hence it has been, for the most part, assumed and described to be a part of the fifth; but in the dog it does not engage the nerve; it is separate, and is only attached by its anterior extremity to the naso-palatine branch of the second division; while its posterior gives off, or receives, as it may be, the chorda tympani: its characters, too, are altogether different from those of the branches of the fifth. It is thence manifest that it cannot be regarded as an essential, original, or necessary part of the fifth, but only an adjunct, and pretty certainly a part of the sympathetic system; with the main portion of which it is connected by one of its posterior filaments.

After several attempts I succeeded—and for the accomplishment of the experiments which I am about to relate, I take this opportunity to make my acknowledgments to the two friends who assisted me; Mr. Williams, Lecturer on Chemistry, and Mr. Thomas Hart, Conservator of the Museum in the Medical School, Park-street; without whose patient, cordial, and judicious co-operation, as well in them as in my other experiments my attempts must have failed—I succeeded in the removal of the ganglion from both sides. In order to do so it is necessary to open the zygomatic fossa, by displacing the zygomatic arch, and the coronoid process of the lower jaw, with the insertion of the temporal muscle; that done, the superior maxillary nerve may be exposed, lying upon the pterygoid muscle; and on drawing aside or raising the nerve, the ganglion will be found beneath it upon the muscle: the deficiency of the wall of the orbit, and the

consequent size of the fossa, afford abundant room for accomplishing satisfactorily the several steps of the operation.

I have thus twice extirpated the ganglion from both sides; and in both instances the animals tasted acutely afterwards. We must then abandon, as groundless, the idea that taste depends, whether for its existence or perception, upon the presence of the ganglion or the chorda tympani, and seek another office for those parts.

The conclusion that taste is independent of them, is confirmed by the existence of the sense, to a very high degree, in animals in which neither ganglion nor cord has been discovered,—for instance, birds; and if those parts have any connexion with the sense, it must be by some other relation than that of the media of perception. That they have a connexion I am strongly disposed to think, because in the animals in which they exist, they are connected especially with those nerves, which will presently appear to be at all events the chief media of perception to the sense; and because, where they are absent, the seats of the sense are probably less numerous, and the apparatus more simple. It is necessary to suppose the existence of some superadded provision, else how is the sympathetic action of the several parts of the apparatus—for instance, the rapid flow of saliva from the impression of a sapid agent, to be explained? but at present this is but speculation, and premature.

It next occurred to me that taste, whatever be its real nature, may be a sensation perceived through the ordinary nerves of the parts where it resides, viz. the palatine and lingual branches of the fifth; and that the question might probably be decided by the section of those branches. For this purpose, the dog also offered a favourable subject, inasmuch as an interval of some lines exists between the origin of the naso-palatine nerve, and the attachment to it of the extremity of the ganglion; and thus an opportunity was afforded of cutting the nerve between those points, without interfering with the ganglion or its connexion. I performed the experiment in two modes: in two dogs I simply cut the lingual branches below the jaw, and the palatines at the interval described, by which proceeding the influence of the ganglion over the latter was not interrupted; and in two others, at the same time that I cut the palatines, I also removed the ganglion; and in both cases the result was *quam proxime* the same, viz. that taste was very nearly obliterated, though sufficient evidence of its presence was still manifested to compel me to admit its existence. The effect produced was, that the animals, which had pre-

viously displayed the usual disgust at the *coloquintida*, no longer manifested any, but only ceased to eat food embittered with it: they would eat several bits in succession, and then refuse to take more, or drop the bit, taken, from the mouth, and take presently a clean bit if offered to them.

I examined two of those animals—one of each—after death; and I found the nerves so fairly divided, that the experiments appear to me unexceptionable. I must also add, that they were accomplished without injury to any other nerve than those mentioned, with the exception of the masseteric branch of the fifth, and part of the superficial temporal, which were of necessity divided; but neither the buccal branch, the infra-orbital nerve, nor the portio dura, was injured. All positive conclusion from them must therefore apply to the palatine and lingual branches of the fifth. They confirm, in the first place, the conclusion already drawn with regard to the ganglion and the cord. In the second, they prove positively that the palatine and lingual branches are, in the mammalia, media, and probably the principal media, of taste; so much so, indeed, that in the first instance, in which the experiment was made after the first method, and in which the palatines were divided on both sides within the same day, the dog seemed absolutely indifferent to a strong solution of the *coloquintida* poured in quantity into the mouth and fauces; but the animal had received a severe shock, and that the *absolute* indifference to the bitter was due to the shock, appears to me satisfactorily shewn by the result of the experiment when differently conducted, *i. e.* when an interval of several days was allowed to intervene between the two operations; in which case the effect was such as has been detailed. It should be known, in order to complete the latter inference, that as, on the one hand, when the lingual branches alone are cut, taste seems impaired; so, on the other, the same result is obtained, when the palatines are the nerves divided; a fact which I have had an opportunity of witnessing in the course of the preceding experiments. In the third place, they shew, that it is as branches of the fifth nerve itself, and not in virtue of their connexion with the spheno-palatine ganglion, that the palatines act as media of taste. And, lastly, they indicate, in the subjects of experiment at least, another medium.

For the performance of this office, two sets of nerves offer: either the other branches of the fifth, distributed to the mouth, or the glosso-pharyngeals. There does not appear reason to suppose that the

former take part in the function; because, first, in the human subject, in which alone we can hope to be able to decide the point, taste is certainly not enjoyed by other parts of the mouth than those already mentioned; and therefore other branches of the fifth than the palatine and lingual are not likely to be connected with it; and secondly, because in some of the experiments upon those, the buccal branches also have been divided, and the result was the same. There remain, then, only the maxillary branches, and the filaments of the lingual not distributed to the tongue, and, they being likewise consumed in parts devoid of taste, it is to be inferred that they also are not associated with it. On the other hand, the manner in which the glosso-pharyngeal nerves are distributed in all animals, but more particularly in birds, and especially in parrots, can leave no doubt that they fulfil in all a function of sensation; and as well the manner of distribution, as the disproportion between them and the lingual branches of the fifth in the parrot, which manifestly tastes by the tongue, would lead to the inference, that in that bird the glosso-pharyngeals are the chief, perhaps the sole, nerves of taste to that organ; and here again experiment alone can decide. This might probably be accomplished upon the parrot; but I have not had an opportunity of attempting it. I have, however, succeeded, I think, in determining the point upon the dog. In one, upon which I had before divided the palatine and lingual branches of the fifth, on both sides, with the effect already described, I afterward cut the glosso-pharyngeals also; and I believe, so far as a single experiment can decide the question, that the animal was then absolutely tasteless. On the fourth day after the operation, I tested him with the *coloquintida* twice within a few hours, and each time he ate, without hesitation, a meal of meat containing so much of the bitter, that I fear it caused his death: at all events he sickened, an hour or two after the second meal, and did not recover.

My experiments, therefore, justify the inference, on the one hand, that the sensation of taste is perceived through more nerves than one, and, on the other, that the glosso-pharyngeals, though not the sole or special media of its perception, have yet a part in the function, and that they are nerves of taste as well as the lingual and palatine branches of the fifth; and if this conclusion be confirmed, the difficulty furnished by the disposition of the fifth nerve in inferior animals, as an objection to its gustatory functions, is still further removed; and we may feel at liberty to estimate the

relative gustatory properties of the two nerves according to their relative development and distribution. The result just stated, further, furnishes a possible solution of those obtained by Panizza, supposing him to have operated on the glosso-pharyngeal nerves; inasmuch as were the faculty, as exerted through the fifth, weaker, and that through the other nerves more active in the subjects of experiment, the result might be easily explained; but I must repeat, that I incline to the opinion, that he either did not operate on those nerves, or that, if he did, he divided only their pharyngeal portions.

In conclusion, I feel justified in drawing the following inferences from the experiments and reasonings which have been detailed: 1st, that taste is a special sensation; 2d, that it enjoys two media of perception; 3d, that its media of perception are the glosso-pharyngeal nerves, and the lingual and palatine branches of the fifth nerves; 4th, that the glosso-pharyngeal nerves are not its special media; 5th, that the latter nerves both are sentient, and influence muscular action; and 6th, that the sphenopalatine ganglion and chorda tympani have no influence upon either the existence or perception of the sense.

ON THE EMPLOYMENT OF TAR- TARIZED ANTIMONY

IN INFLAMMATION OF THE MUCOUS
MEMBRANE OF THE LUNGS.

To the Editor of the Medical Gazette.

SIR,

I HAVE inclosed the following case as an instance of the decided effect of tartarized antimony in allaying inflammation of the mucous membrane of the lungs. Hitherto the use of this medicine has been, in a great measure, restricted to cases of inflammation of the cellular texture of the lungs; and even in these cases its use has not been so general as the statistical report contained in the GAZETTE, vol. ii. p. 191, with other unimpeachable documents, would justify. In fact, there is but one solitary circumstance which contra-indicates its use—viz. an irritable state of the mucous membrane of the alimentary canal; and the symptoms of this affection are so palpable that the slightest observation will detect it.

Without entering upon the question whether bronchial inflammation be an

exciting cause of tubercular phthisis, (an opinion, however, which has been decidedly negatived by M. Louis,) it will not be disputed, that in this country, particularly in our large towns, a considerable proportion of the cases of acute and chronic bronchitis occurs in persons who give every indication of a prevalent tubercular diathesis, so far as we can judge from a general want of tone, with absent or distant respiratory murmur under one or both clavicles; and in these cases, the removal of inflammation by active depletion, or mercurial action, is frequently followed immediately by the rapid development of tubercles. The tartar emetic treatment, under such circumstances, will, I am sure, be prized by those who have an opportunity of witnessing its marked results.

Another object in sending the case, is to introduce to the notice of the profession a preparation which has not, so far as I am able to learn, been yet used in this country; but which will, I am convinced, be numbered amongst our valuable therapeutical agents, so soon as its beneficial results are more extensively known.

On a future occasion, I hope to have the honour of submitting to your notice some cases illustrative of the action of the bromide of iron on the processes of absorption and nutrition. These cases, however, contain nothing more than an account of results. Our knowledge of the physiology of nutrition is at present so limited, that any reasoning on the pathology of that function must be purely hypothetical, and therefore unsafe.—I beg leave to subscribe myself,

Sir,

Yours very respectfully,

GEO. KEMP, M.B.

Cheshunt, Herts., Nov. 12, 1836.

October 26, 1836.—E. Huntley, æt. 27, cook, has been suffering for the last week from a severe cough, with which she has for some years been frequently harassed. On account of the great distress occasioned by speaking, I am unable to obtain a connected history of her case, but learn from her sister that she has been under the care of a medical man in the neighbourhood for the last few days, who applied a blister to the chest, which is still open, and that yesterday she was attacked with shivering;

since which time the cough and dyspnoea have much increased.

At present (3 P.M.) the difficulty of breathing is very considerable, the countenance anxious and flushed, the lips livid, and the cough incessant. Pulse 120, irritable; expectoration excessively viscid. She does not complain of pain in the chest, and can bear firm pressure in the intercostal spaces.

Percussion elicits a dull sound over the whole chest, and the stethoscope discovers every modification of mucous râle, both anteriorly and posteriorly, with crepitant râle over a small space in the left infra-clavian region.

From the history of the case, so far as I could obtain it, the general appearance of the patient, and the situation of the crepitant râle, I presumed that a tubercular diathesis existed, and preferred the tartar emetic treatment to blood-letting, or exciting mercurial action.

Half a grain of tartar emetic was accordingly ordered to be taken immediately, out of camphorated water, and to be repeated every four hours.

27th.—Unable to see her till 8 P.M., when I found her much better in every respect. She complained of nausea, but had not vomited; pulse 80, soft and compressible; cough less frequent; expectoration less viscid, and beginning to assume a detached rounded form. Mucous râle still considerable, but the crepitant râle has disappeared. She was directed to continue the tartar emetic.

28th, 11 A.M.—The cough has not troubled her much during the night. The last dose of the tartar emetic occasioned vomiting. Mucous râle much diminished. The tartar emetic to be discontinued; and as the bowels are rather constipated, one ounce of castor oil is directed to be taken immediately. Four grains of James's powder are directed every four hours.

29th.—Much better; has only coughed two or three times within the last twenty-four hours.

30th, 9 A.M.—A remission of inflammatory symptoms occurred this morning about 4 o'clock; the cough has been very frequent since that time. At present the dyspnoea is considerable; the mucous râle is prevalent over the whole chest, but no crepitation can be discovered. The expectoration has

again become extremely viscid and transparent; pulse 90, irritable, but yielding to pressure; tongue furred, but red at the margin. She does not complain of any pain in the chest, but the mucous membrane is so irritable, that every effort to speak occasions cough. One grain of tartar emetic is ordered immediately, to be repeated every four hours. A blister is also directed to be applied over the sternum.

5 P.M.—Having just taken the tartar emetic, complains much of nausea, but there has been no actual vomiting; cough less troublesome. Pulse 80.

31st, 10 A.M.—Has slept well; the cough is considerably less troublesome, and the expectoration having again assumed an opaque appearance, is rejected in distinct pellets, with little effort. Pulse 80, soft and compressible. The mucous râle is not extensive, and constantly shifting; the tongue is slightly red at the margin, and the last dose of the tartar emetic occasioned vomiting; it is therefore discontinued.

Nov. 1st.—All inflammatory action has apparently subsided; the respiration is in many parts of the chest quite healthy; it is, however, indistinct under both clavicles, particularly the left.

2d.—The patient now complains of nothing but debility, and having previously seen great advantage derived from the use of the bromuret of iron, in cases where a tubercular diathesis appeared to exist, she is ordered to take a grain and a half three times a day, dissolved in distilled water.

This preparation is analogous in its effects to the ioduret of iron, which is certainly one of the most valuable tonics we possess. One great objection to the administration of the ioduret exists in the circumstance of its undergoing rapid decomposition immediately on its being exposed to the atmospheric air. The bromuret may be kept in a state of solution with distilled water for many weeks, without the occurrence of any appreciable decomposition. The solution is the only form in which this salt can be given, on account of its great deliquescence. I have generally ordered it in a solution of the same strength as Dr. Thompson's solution of the ioduret, viz. three grains of the bromide to a drachm of distilled water, of which thirty minims are taken at first twice, and subsequently three or four times a

day, the patient being careful to keep the bowels regulated by means of castor oil.

As I have had great difficulty in obtaining the preparation in London, I may just mention that it has been very carefully prepared for me by Mr. Johnson, chemist and druggist in this place.

THE PHYSIOLOGY OF SALIVATION.

By T. G. HAKE, M.D.

Physician to the Brighton Dispensary, &c.

THERE has been no greater impediment to science than the mind *itself*, which, instead of calmly awaiting the results of its *researches*, glides anxiously forward in anticipation, and, in so doing, passes over the truth, which was too simple, too similar to the things amid which it lived, to be observed. So vast is the range of thought, that if it stray beyond the boundaries of its subject, as liable to do, it unconsciously betrays itself into remote analogies, which perform their functions apart, and are too beautiful, perhaps, to be refused in illustration of an inquiry which the intellect may have proposed to elucidate.

In the sciences connected with physic, as in all other things, the many are influenced by the few; and the creeds of the medical world may be traced to sources which are limited in comparison with the numbers who adopt them. It is the province of some to collect the most perfect facts, concentrating all their reason in vision—these are the working classes of philosophy; and of others, to mentally resolve facts into their elements, and at one glance to compare them with all knowledge, in order to detect a way through those labyrinths, which afterwards they have to traverse.

In physiology, this influence of the few is yet more strongly felt than in physic, for he who carefully practises the latter art arrives so nearly at general principles, by the experience of a constant return of like facts, that truth may be said to have taken a hold on the instinct before reflection has confirmed it, and only awaits the approval of authority or reason, to be

changed from a sentiment to a perception of its reality.

But in physiology, because men do not perpetually reflect, the inexperienced mind is very apt to be seduced. The details of this science are hidden from us, so that facts the most uninteresting are received, and theories the most inappropriate adopted, to swell its annals.

The writer of this paper has before defended the absorbent system against those who would render it accountable for the mischief produced by many poisons, whose action is transmitted by the nerves; he will now, therefore, preface his *theory of salivation* with a *view only of the manner* in which the venereal virus acts, and mercury, the cause of ptyalism.

The great functions of a nervous system are produced in the extremities of nerves; they may be impeded by interruptions in the trunk, but the performance of the grand duty resides in the terminal branches, where they expand into the membranous form, and mingle inseparably with the tissues which they govern.

By means of a nervous system, the disorders of one organ may be translated to another, similar in structure, their sources of nervous power being related.—On this principle becomes explicable the venereal progress: it commences in mucous membranes, and, through its nerves, attacking the glandular structure of the part, excites derangements in adjacent glands, or confining itself to mucous structure, affects distant mucous tissues.

But mercury, similar in its mode of action as regards the system which it affects, has a directly opposite effect to the venereal virus; the one being permanently sedative, the other stimulant in its powers. Mercury pursues the same track in supporting, as the virus does in undermining the nervous system; and so far does this analogy extend, that the depression consequent on mercurial action disorganizes, when pushed too far, the same tissues as those which suffer from the virus, and causes the like affections; such, for example, as glandular enlargements, ulcerations, and cutaneous eruptions.

When mercury is internally administered, in quantities proportionate to the final causation of ptyalism, the following

processes occur. A stimulant acts by contact with the expansion of sympathetic nerves on the stomach and intestines. As it is propelled along that diversified line of organization, it acts on all its functions in a similar manner, but with different results. In the duodenum it urges the nervous battery with which it is in contact to increased power, stimulating the very glands themselves, whose ducts open into the upper bowel, and so causing an increased secretion and outpouring of pancreatic juice and bile; the same being produced through the medium of nerves extended between the mucous surface and the glandular bodies whose function is to secrete these fluids. In the meantime, the mercury being pursued, its impulse reaches the remoter parts of the sympathetic system, and on its terminal branches, the expanded seats of function, acts. The secretions are now more plentiful, and the solids are absorbed, but the principal change which is taking place in the system at this stage, is the provision instituted in the blood to meet the great demand for bile and pancreatic juice, the general harmony of the secretions having been compromised by the specific action of the stimulant on the hepatic and pancreatic glands.

The bile being excrementitious, the system can meet its increased secretion to only a limited extent. The quantity of this fluid existing in the blood in an elementary state may for a time answer the demand made in the duodenum, and the solids yielding to the absorbents may prove a further resource; but this can continue only so long as the sources of bile are not dried up. But, fortunately, organized matter not only becomes insensible to every stimulant after a certain duration, but even depressed below its standard tone. In accordance with this principle, the liver refuses to overact its part before the scarcity of its secretion is appreciated in the system. The pancreas, on the other hand, secreting a fluid easily yielded by the arteries, and daily replenishable from that inexhaustible source, the food, bears the mercurial impulse longer, and when at length it becomes insensible to the stimulant, the habit of elaborating pancreatic juice, or rather its components, in the blood, is established, and maintained by the tonic action which

the mercury still supports in the absorbent vessels.

It now appears, that the action of mercury, primarily on the pancreas, and secondarily on the absorbents and lacteals, causes the circulation to be overloaded with an excess of pancreatic fluid, which does not find egress at the pancreas any longer, that organ being unable in its depressed state, the consequence of over-excitement, to secrete even its usual quantity of fluid. It is essential, however, to the equalization of the secretions, that this excess of abdominal saliva should be evacuated, as long as its production continues. It therefore becomes a question, through what channel it may be expelled; and as the salivary glands, that is, the parotid, submaxillary, and lingual, are similar to the pancreas in structure, and the fluids which all secrete are nearly alike—moreover, these former organs having received the mercurial impulse subsequently to the pancreas, and being consequently under its influence, while the pancreas has sunk into its atonic state—they are in every way adapted to relieve the blood of its excess.

It is not thus maintained that pancreatic juice, but that saliva, is evacuated by this system of glands, for the former contains ingredients which probably the latter does not. For these there are uses in the system, they being animal matter; they may be deposited for use, or evacuated through other channels; while the salts, in a state of solution, are plentifully excreted at the salivary glands.

This is the physiological history of salivation.

CASE OF
FISTULA LACRYMALIS,
TREATED AFTER DUPUYTREN'S METHOD.

To the Editor of the Medical Gazette.

SIR,
THE question has often been asked, what becomes of the tube, (that so extensively used by Dupuytren) after it has been passed into the nasal duct, in cases of fistula lacrymalis? The difficulty of tracing these cases to a termination has, doubtless, stood in the way of a satis-

factory answer. The following case will, at least, answer for itself, and will prove that the termination of such cases cannot always be so favourable as is sometimes stated; although, for aught I know to the contrary, it may still be considered as efficient a mode of treatment as any other with which I am acquainted.

Mrs. S. consulted me in July, 1833, complaining of considerable irritation in her right eye, tumefaction over the situation of the lacrymal sac, and a continual flow of tears and mucus down the face. She had been annoyed in this manner for some months, the integuments over the sac becoming swollen, inflamed, suppurating, and then gradually subsiding. The disease returned periodically, and always about the time of menstruation. The simple antiphlogistic treatment was at first recommended, with temporary relief. The affection continuing, it was thought advisable to introduce the style into the nasal duct, which I did without difficulty. This she wore for about six months, at the expiration of which time she expressed a strong desire that something more might be done, as the tears continued to run over the cheek, so as to torment her considerably, although her sufferings had, on the whole, been much lessened.

To gratify this desire, I thought it proper to remove the style, and to insert instead of it one of the silver tubes. This was accomplished with great facility, so slight was the obstruction. On the next day the aperture had healed over, there was nothing visible, and she expressed herself very comfortable. She continued to go on well, and soon ceased to complain. The tears now passed off through the duct, and she expressed herself highly delighted with the result of the treatment, considering herself as cured. From this period I saw her occasionally, and she continued to regard herself as quite well, until about six or eight months since, when she again began to complain of uneasiness in the corner of the eye, and said, that on blowing her nose she thought she perceived the motion of the tube. There was a degree of tenderness and watery state of the eye, and a small capillary aperture was visible, just over the sac, through which the lacrymal fluid appeared to ooze.

Not perceiving that any thing more

could be done, I advised her to wait patiently, until some further change was observable. About two months since, she was startled one morning, while lying in bed, at experiencing a sudden sense of choking, as if from some foreign body in the throat, and which, when ejected, proved to be the remains of the tube which had been introduced into the lacrymal sac *three years before*.

I found that a considerable portion had been corroded—more than one-half—the broad upper portion being entirely gone, or else separated from the lower, and remaining behind. She expresses herself easier since it came away, and has not much to complain of, except the discharge of the tears through the little fistulous opening in the sac, which, however, is not very distinct.

I am, sir,
Your obedient servant,
JOHN WALKER.

Manchester, Nov. 17, 1836.

ANALYSES AND NOTICES OF BOOKS.

“ L'Auteur se tue à allonger ce que le lecteur se tue à abréger.”—D'ALEMBERT.

Hygiène Publique ; ou Mémoires sur les questions les plus importantes de l'Hygiène appliquée aux Professions et aux travaux d'utilité publique.
Par A. J. B. PARENT-DUCHATELET,
Membre de Conseil de Salubrité, &c.
Deux Tomes. Paris, 1836. Bailliére.

THE name of Parent-Duchatelet will long be remembered in connexion with the extraordinary work which we lately noticed—his Statistical and Physiological Account of Prostitution in the City of Paris; but the volumes now published are, perhaps, not less extraordinary, from the variety and extent of their subjects: they form altogether the richest mine of information, on every thing relating to the public health, that has ever been offered to the professional world. There are not less than about thirty papers here, which have, for the most part, been drawn up at the request of the French government: they are the result of indefatigable labour bestowed on matters of research, many of which would deter most inquirers, not by their

difficulty alone, but by the 'disgust which they could not fail to excite; for instance, the elaborate *Essai sur les Cloaques ou Egouts de la Ville de Paris*, and the *Rapport sur le Curage et l'Assainissement des Egouts*, &c. But on the other hand, how many of the subjects are there not as attractive as they are important? We may cite, for example, the articles, on the Methods of respiring deleterious Gases with impunity; on Artesian Wells; on the Purification of Dissecting-rooms; on Inhumations and Exhumations; on Knackeries and the methods in use for drying dead horses; on feeding pigs with horseflesh; and several essays on the influence of certain trades on the health of the workmen.

To do justice to the contents of these volumes would require more ample space for analysis than we could well afford; some, however, of the topics we have touched on before, in certain notices of the *Annales d'Hygiène*; and it may be possible, certainly it would be desirable, to take up some of the others on future occasions.

Most, if not all, the essays and reports in this collection, have been gathered from the periodical just mentioned. But the reader will readily appreciate the amount of his obligation to the spirited publishers, who have so liberally collected into a moderate compass, and rendered procurable at a very reasonable expense, what has hitherto been diffused through numerous volumes, accessible, in general, only in our larger libraries.

MEDICAL GAZETTE.

Saturday, November 26, 1836.

"I licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

HOMŒOPATHY ;

FURTHER ILLUSTRATIONS OF ITS NATURE.

Our last specimen of Homœopathy was confined to the effects produced by that potent drug *charcoal*—a drug which, though taken only in the millionth of a grain, excites so very extraordinary an

460.—XIX.

influence over both body and soul. Let us now notice some other articles of the Hahnemannian materia medica; and lest it should be said that we select only those of inferior note, keeping the grand remedial agents in the background, we shall take *gold* and *silver* to begin with. Gold, be it known to the uninitiated, is prized by Hahnemann as a sort of *summum bonum*,—in which there are many ancient and modern authorities to coincide with him; it is a sort of *elixir vitæ*, with such powerful virtues as no other substance possesses: in fact, as Geber and the philosophers of alchemy maintained, gold is the delight and the staff of life—*materia lætificans et in juventute corpus conservans*. Hahnemann admits this.

But before we enter on the virtues of the substances just named, let us premise a few words on the nature of our argument. Our account of the homœopathic symptoms is, on this occasion as on the last, wholly derived from Hahnemann's own books. We quote his *Pure Materia Medica*, (so called, we presume, from its astounding *impurity*,—"Lucus à non,") from the authorized version of Jourdan—himself a worthy homœopath. We give the number of each symptom, in order that, if we misrepresent (as we surely have no desire to do), we may be censured and exposed. It will not do for the silly supporters of homœopathy to say, in general terms, that we mis-state, or that we do not understand Hahnemann. If we mis-state, let us be corrected; if we do not understand, then is Hahnemann not to be understood: he mystifies; he does not speak in intelligible language. We take up his books, presuming that they are addressed to persons of ordinary common sense; and we put upon the words employed the only interpretation of which they admit. But enough: now for the precious metals.

Perhaps we may as well begin with

X

Silver; not only as it comes first in order, but as the display of the virtues of this milder metal (however in itself most potent) may prepare us for, and prevent us from being dazzled with, the greater glories of gold.

The symptoms which follow, we should observe, are not produced by any vulgar salt of silver—such as the nitrate, which is sometimes used by allopaths — but pure virgin metallic silver: and, spite of all that may be said as to metallic silver not being soluble in the stomach, Hahnemann says he cares not: he throws himself on his *experience*; takes his dose, not containing the ten-thousandth part of a grain, and feels, among other effects, the following:—

14. Great itching in the corners of the eyes.

15. Great itching of the outer ear, obliging him to scratch till the blood comes.

48. Insupportable itching of the head and other parts of the body, as if from the creeping of some kind of vermin.

This reminds us of the symptoms of a millionth of a grain of charcoal: but it would seem that most of the homœopathic remedies make certain parts itch. Here is something more original;

46. Walking abroad causes fatigue and general heat, without sweating, but with uneasiness, as if one's clothes were too tight for him.

50. Dreams about things that happened during the day.

27. During the night, a rumbling in the belly, and *émission de vents*.

31. Almost every night—*une perte de semence*.

34. A cough in the morning.

The last of the symptoms experienced by Hahnemann from metallic silver, is—

66. Ill humour!

But it is satisfactory to know that a little more of the metal would cure this unpleasantness; or better still, if *gold* were taken.

Gold, which we must next notice, is a sovereign remedy with the homœopaths. It is said to have an extraordinary power of curing “melancholy attended with a propensity to suicide.” The allopaths do not deny it this property when given in a tolerable dose; but the homœopaths say that the quadrillionth of a grain! is sufficient: to this the vulgar medical world demurs.

But to hasten to the symptoms produced by metallic gold: and the *symptoms*, be it recollected, are everything with the homœopaths; they are the disease itself. It is necessary to premise that the symptoms about to be enumerated are said to have been produced by a very small part of a grain of a dilution of gold to the quadrillionth. “Je n’emploie” says Hahnemann, “plus qu’une très petite partie d’un grain de la dilution au quadrillionième!”

We are now to consider the great founder of modern medicine as having swallowed this most potent dose: observe the effects, for they were experienced by *himself*.

75. Pain in the groin, as if a gland had become swollen there.

76. An *inguinal hernia* makes its appearance, attended with great pain, like cramp: flatus seems to penetrate into the hernia.

What thinks the reader of this effect of the quadrillionth of a grain of metallic gold?—*inguinal hernia*!—but let it pass.

81. Prodigious evacuation of the bowels in the evening (at the end of ten hours).

82. *Diarrhœa* in the night, with much heat of the rectum.

83. *Fæces* very abundant (*très-volumineuses*) with difficulty of passing them in consequence.

85. More urine discharged than the quantity of drink taken.

Then follow a set of symptoms which we cannot possibly venture to translate: they must speak for themselves.

86. Le matin, apres s'être levé, violentes érections et desir de coït.

87. Très-grande exaltation de l'appetit vénérien, qui auparavant avait été pendant long temps assoupi.

88. Erections nocturnes, plusieurs nuits de suite.

89. Ejaculation, trois nuits de suite, qui n'est pas suivie de faiblesse.

90. *Vulsion très-douloureuse dans la verge d'avant en arrière, &c. &c.*

Such are some of the beastly phenomena expressly attributed to a quadrillionth of a grain of metal. Is the reader awake, and still dubious of the gross humbug—of the fraud, attempted to be practised by these impudent impostors?

Leaving, them, however, in their beastliness, let us see some other effects which they pretend to trace to their invisible dose of leaf-gold.

98. During expiration a grumbling in the upper part of the chest, which descends even into the lower belly and the groin, followed by very rapid palpitations, lassitude, and anxiety; then a sensation of sinking.

Wonderful, truly, is the operation of this great agent; for we believe there never was such a *symptom* as this heard of since the world began!

But here are other effects of the invisible golden dose:—

133. Alarming dreams.

134. Frightful dreams of robbers, with cries in the sleep.

135. *Dreams of dead men!*

136. Awake in the midst of dreams.

139. *Toutes les nuits, rêves et érections.*

155. Melancholy—depression.

We forbear to quote the no less extraordinary symptoms described by other homœopaths, all of which are carefully treasured up by Hahnemann, and given to the world appended to his own. The reader is now sufficiently aware, from the express experience of the founder, of the great importance of gold, a substance which he and many other allopaths, who have hitherto been looked to as high authorities, always considered as a

wholly inert substance—a substance on which the stomach and its juices had no power of acting.

We must certainly henceforth be on our guard how we introduce gold into our mouths: we are warned of the danger of fastening our teeth with wire of gold, or stuffing them with leaf. The consequences of swallowing even the sextillionth of a grain might be the death of us, or make us wretched for life. It would cause inguinal hernia, or purge us to desperation; in the evening excite certain parts of the system more violently than if we had taken cantharides; make our nights miserable with dreams of robbers and dead men; and our days deplorable with a feeling of suicidal melancholy. All from the accidental deglutition of an invisible quantity of metallic gold!

A word or two on another substance, which the world has hitherto thought it might trifle with, and swallow largely with impunity. Capsicum! Beware, ye eaters of *devilled* delicacies, ye lovers of curry, and even ye who meddle with pickles! Hear what dire effects have been produced by “a very small part of the millionth of a grain.”

103. *Umbilical hernia*, with violence and pain.

111. The anus itches (after three, four, eight hours).

112. Lancinating, smarting pain in the anus, during a diarrhœal discharge.

155. Discharge of blood through the anus, during four days!

135. *Erection, le matin, dans le lit, sans pensées voluptueuses.*

136. *Violente erection, le matin, en se levant, qui ne peut être apaisée que par l'eau froide.*

137. *Pendant des badinages amoureux, tremblement affreux partout le corps!*

Have we given enough of these elegant extracts? For the present, at all events, we pause, and leave it to the Uwinses, the Everests, and the other neophytes, to explain, or to sit in silent admiration of, their great master. All

that we have said is justified by reference to Hahnemann's own book: we have given the *symptoms* as we have found them; and we defy the whole race of his pitiful hangers-on to prove that we have, in a single instance, garbled or misquoted him.

ROYAL COLLEGE OF SURGEONS.

WE gave the substance of the following important notice a fortnight ago. The regulation, we understand, applies only to the recognized teacher, and does not extend to those employed as demonstrators,—the latter not usually coming within the cognizance of the College:—

The Council of the College, at an extraordinary meeting, on the 1st instant, established the following Ordinance, relating to the recognition of the certificates of teachers of anatomy and surgery in England and Wales:—

That in future no person be recognized by this College as a teacher of anatomy, physiology, and pathology, or in surgery, in England and Wales, until he shall have undergone an examination before the Council of the College on two separate days. The first examination to be in anatomy and physiology; the second in pathology, and on the principles and practice of surgery.

That no fee be demanded for these examinations; and that the recognition of the College be conveyed in the usual form of a letter from the Secretary.

By order,

EDMUND BELFOUR, *Sec.*

November 18, 1836.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, Nov. 22, 1836.

MR. EARLE, PRESIDENT, IN THE CHAIR.

AT the meeting held this evening, a paper, communicated by Mr. Stanley, was read: it was entitled—

"On some of the Forms of Atrophy of Bone.
By Thomas Blizard Curling, Assistant-Surgeon to the London Hospital, and Lecturer on Morbid Anatomy."

The author of the paper employs the

term atrophy to express all those changes evinced by loss of substance, unaccompanied with any alteration in texture or organization, and without any reference whatever to the morbid action which produces it; and several forms of atrophy of bone, which are but imperfectly understood, or which have not hitherto been noticed by pathologists, are the objects of his inquiry. He first alludes to local atrophy, in which the earthy and animal constituents are removed equally and together; and he instances as an uncommon variety, and as being of considerable interest in surgical pathology, a case of partial dislocation of the os humeri forwards, with atrophy of the head of the bone and inner edge of the glenoid cavity of the scapula.

Instances are mentioned in which the particles entering into the composition of bone, both hard and soft, are universally decreased, and the bone thus rendered smaller and lighter, which, in order to denote the direction of the wasting, and to distinguish it from another form, the author proposes to term *concentric atrophy* of bone.

Some cases of this form, arising from loss of function and deprivation of nervous influence, are alluded to.

Mr. Curling next proceeds to notice the effects of a diminution in the normal supply of blood. After some observations, the purport of which is to show that, in consequence of a collateral circulation being readily established, atrophy from this cause only takes place in organs supplied by one or two large arteries, as the kidney, and that the operation of tying the vessels to arrest the growth of tumors, is only applicable to such growths as are supplied by a few large arteries, immediately as they enter the diseased structures, he proceeds to inquire whether the bones may not, in consequence of accident or disease, sometimes have their circulation interrupted at the point where the vessels are about to enter their structure. It occurred to him that, in fracture of the long bones, one part must have the supply which it derives from the nutritious artery entirely cut off; and although there is a free communication with the periosteal vessels, yet the minute canals through which they pass being of a dense unyielding nature, these vessels must be prevented from undergoing that rapid increase in size, which, in the soft structure, constitutes so efficient a provision for a due circulation. Numerous sections of fractured cylindrical bones were accordingly examined, in order to ascertain if the ends which were deprived of their supply of blood from the nutritious artery suffered a corresponding degree of atrophy: this was found to be the case. Thus in femurs fractured below

the entrance of the nutritious artery, the interior cavity of the inferior extremity was enlarged, the cancelli expanded, and the walls thinned, a form of atrophy which the author proposes to distinguish by the term *eccentric*. A similar alteration was also observed in fractured tibiae, while, in a humerus broken above the entrance of the nutritious artery, the upper portion was the seat of this change.

Mr. Curling further observes, that the division of a bone, with its circulation diminished, and actually wasting in consequence, must be in a condition most unfavourable to unite, shewing the necessity for the provisional callus described by Dupuytren, for the security of the limb until the circulation in the bone is re-established. This species of eccentric atrophy is not constantly met with, being absent under the following circumstances:—

1. In bones recently fractured; because the process by which atrophy is accomplished must necessarily be gradual.
2. In bones long united; because a collateral circulation is subsequently established, and the previously existing lesion repaired.
3. In bones fractured during the period of growth; because the circulation being at this time more active, and the vessels and canals through which they pass larger, the circulation is re-established before any visible degree of atrophy can occur. Occasional variations both in the number, size, and situation, of the nutritious arteries, are also mentioned, as tending to prevent this change from being constant. Upwards of twenty preparations, in different museums of the metropolis, are distinctly referred to in proof of the justness of the author's views.

After briefly noticing the pathological investigations of Sir Astley Cooper, in regard to the neck of the thigh-bone, allusion is made to the state of the head of the femur after fracture within the capsule, where, when the periosteum investing the neck is torn through, the circulation is diminished to a greater extent than in other descriptions of fracture, so that the whole of the detached bone suffers, and the atrophy, instead of being only eccentric, occurs throughout its texture, the bones becoming insufficient to fill the acetabulum.

The author treats next of the atrophy of old age, which he likewise describes as *eccentric*, and generally commencing first in the neck of the femur. He mentions that the animal tissue is usually removed first, so that the bone is rendered brittle, but that in some instances the earthy parts are removed before the animal tissues; which accounts for the head of the femur sinking down upon its shaft. He remarks that a similar change sometimes takes place in the head of the humerus, and

notices a preparation in the collection of the London Hospital, where the head of this bone is depressed, and its shape altered, from the eccentric atrophy of old age, attended with softening.

The remainder of the paper is occupied with an inquiry into the nature of the disease called *mollities ossium*. The case of a female who died of this affection in the London Hospital is related, and the pathological condition of the bones minutely described. A table is given of 16 cases, showing the sex, age, and authority for each; and from a review of the facts thus collected the author is induced to conclude, that the disease commonly occurs in females who have borne a family: that it usually proves fatal from the age of 30 to 40: that it never appears before the age of puberty, and very rarely after the age of 50: that in general the internal organs are healthy, and the various functions duly performed, unless interfered with by the distortion: that its progress varies greatly, lasting sometimes for only a few months, in other instances occupying many years; and that it is nearly always accompanied with pains of a severe character.

Mr. Curling considers this disease as a species of the eccentric atrophy of bone, commencing invariably from the interior in the flat bones, affecting first the *diploe* and subsequently the external tables: in the long bones attacking first the interior of the shaft, and afterwards extending to the vascular or cancellous extremities, and going on until, if the patient survives, no part of the osseous tissue remains, its place being supplied by an increased secretion of the medulla, invested and retained *in situ* by the periosteum. He attributes the circumstance of the disease being attended in some instances with the utmost distortion without fracture, and in others being expressed by a remarkable fragility of the bones, to a slight modification in the wasting process,—to the more or less rapid decay of the earthy parts as compared with that of the animal constituents. Taking into account the fact that it usually commences in the inferior extremities, and goes on most rapidly in the harder parts, the author is led to regard the disease as the result of defective nutrition, and not of increased activity in absorption. In support of this opinion he points out the analogy which exists between this disease and the atrophy of old age. In both, the atrophy is eccentric, attended with an increased secretion of medulla, and more remarkable in females. In both it is subject to slight modifications, in the ratio of the decay of the earthy and animal constituents, and cases of *mollities ossium* are alluded to, in which, like the

eccentric atrophy of old age, it commenced first in the neck of the femur. Instances are given in which sediment in the urine and calculi had passed, and in which the perspirations were foetid and turbid. These circumstances are regarded as tending to indicate that the blood was loaded with something which it endeavoured to discharge by any of the natural outlets: that there is no want of the phosphates in the system generally, and when taken in connexion with all the facts hitherto ascertained—the age at which it occurs—its being independent of disease elsewhere, its commencing in the lower extremities, &c., to shew that the parts essentially at fault are the vessels that nourish the bone, the impaired function of which is first manifested in the system of the nutritious artery.

In conclusion, the author takes occasion to observe that the remarkable fragility of the bones noticed in connexion with cancer, is sometimes owing to this eccentric form of atrophy.

CLINICAL LECTURE,

Delivered at St. George's Hospital, November 11, 1836,

By DR. SEYMOUR.

GENTLEMEN,—The cases of rheumatism of which I spoke to you some time back, are all well.

POISONING BY ARSENIC.

The case which I mentioned at our last meeting—that of a woman respecting whom I felt some anxiety, under the idea that she had taken arsenic—has quite recovered. I am now inclined to believe that she never took arsenic at all; or (for she stated that she swallowed it in gin) that it fell to the bottom of the glass, and she drank but little of it; or that it was removed by the stomach-pump at the station-house, before she was admitted into the hospital. At all events no symptoms have occurred since, and she is perfectly convalescent.

GONORRHOEAL RHEUMATISM.

The other case about which I spoke at our last meeting—that of Dodson, who laboured under gonorrhoeal rheumatism of thirteen years' duration—is, I am happy to say, something better. The use of the vapour-bath, and the moderate exhibition of the inspissated juice of colchicum, certainly appear to have been attended with benefit. He is able to move the left hand

more easily than at his admission; a blister has been applied to the right wrist, and he begins to be capable of moving the fingers of that hand also. This, it is true, is but very limited relief in such a case, but, inasmuch as it has occurred within the last ten days, I have every reason to hope, that by pursuing the same plan of general treatment, and applying a blister to the affected joints of the hands and feet in succession, we may yet restore a modified degree of movement, and relieve him from the condition he is in at present—that of being a perfect cripple.

DIFFUSE RHEUMATISM, CONJOINED WITH LARYNGITIS.

I may also state that another severe case of rheumatism was admitted in the course of the week, previous to my taking in on Wednesday; and I would finish with that subject before I proceed to the next. It occurred in a man named Allen, in King's Ward, who had been a patient in the house, under the care of the surgeons, for a fracture of the collar-bone. He had got well, and went out during the dreadful weather a few days ago. He was again admitted into the hospital on the 3d November, and came under my care, with acute rheumatism. As the bandages applied for the fracture still remained, I had them taken off, and he was examined, that we might see whether any part of the complaint arose from the injury he had sustained. That was found to be perfectly well, but the rheumatism was of the most severe kind, and the same cause which produced it—viz. the alteration of temperature—also gave rise to some degree of inflammation of the wind-pipe. He laboured under a hoarse, harsh cough, accompanied with a loss of voice, and considerable difficulty of breathing. The rheumatism is the most severe that it has been my lot to witness for several years: it is of a diffuse kind, and affects the arms, the hands, the feet, and the knees. He is totally unable to move, and, added to this, there is the more severe inflammation of the wind-pipe.

Treatment.—I was obliged to adopt active measures. He was ordered to be bled, and three grains of calomel, with one of opium, were exhibited every four hours. On the following day, the blood which was drawn was found to be both buffed and cupped: I never saw blood so much inflamed even in inflammation of a serous membrane. Estimating the clot according to a line drawn perpendicularly to the horizon, I should say that one-third consisted of buffy coat. The blood being in this condition, further depletion was ordered on the following day. I think I mentioned that is an unusual circumstance

to be obliged to bleed frequently in acute rheumatism*, but this patient was bled three times, and on each occasion the blood presented this very remarkable appearance. The other symptoms which marked the severity of the disease became diminished. He was sometimes covered (which is frequently the case in severe rheumatism) with acid sweats. You might ascertain the acid by the sœtor, which was very unpleasant; but, in addition to this, litmus paper, when placed on the perspiring surface of the body, became as much changed as if it had been infused in a vegetable acid. The urine was abundant, and dark coloured, and there were present lithic acid and the lithates. This likewise shewed very great acidity, upon litmus paper being put into it. Some of you saw that to-day. The saliva even in this man is acid.

Now as all these secretions are taken from the blood, one would think that it was an admirable illustration of the humoral pathology; but the last trait, at least so far as the ordinary chemical signs are concerned, is wanting—viz. that the blood drawn does not show a trace of acid on the application of litmus paper. Therefore we must suppose that there must be some alteration from the blood by the secreting vessels, during the period the acid is formed, rather than imagine that it exists free in the blood, and is drawn off in that state by the secreting process, so as to mix it with the different fluids to which I have alluded.

The principal relief afforded by the treatment laid down, has been the diminution of this acid. To-day the perspiration scarcely reddens litmus paper; the acid contained in the urine is greatly diminished; the urine has become clear, and there is no admixture apparently of any of the lithates which were in such abundance when the patient was first admitted. He has had a blister applied to the chest, and the cough has become greatly diminished; his mouth is not sore. He is a great deal better to-day, and there is a fair promise of his recovery.

I mentioned in my first lecture, that in treating acute rheumatism, I resort, in the first instance, to venesection, and subsequently to the exhibition of guaiacum; and you will naturally ask why I differed from my ordinary plan in the present instance. First of all, I know nothing which exercises so great a control over the acid sweats as opium; in the next place, there was some degree of inflammation of the wind-pipe—a far more dangerous disease than rheumatism, and which might have

proved fatal in a short time; and, in the last place, the blood was covered with the buffy coat I have described. Under these circumstances, I thought it better to trust to calomel and opium than to rely on those measures which I laid down before, and which are attended with such rapid success. There is a case in the house of diffuse rheumatism of the ordinary kind, in which the patient has been put on guaiacum; and though she was only admitted last Wednesday, yet she is so much better to-day that I have no doubt she will be well in a couple of days. The case before us is of a more complicated description, and therefore I put the patient on a mode of treatment more decidedly antiphlogistic, and calculated at the same time to allay irritation. Why opium should so act I cannot tell, but it certainly does moderate the secretion of acid.

GOUT.

I proceed now to consider three other cases, which it is curious to find in a hospital—viz. cases of gout. It is very uncommon, in a metropolitan hospital, for one physician to have three cases of gout under his care at the same time; I do not recollect such an instance before. If the rich have their comforts and immunity from hardship, they have, in the shape of gout, something to make up the equilibrium. This disease is almost exclusively confined to the rich—so much so, that in private life a man sees ten times as many cases as a physician to a hospital. We have, however, three cases, and they are in different stages or periods of the disease.

REGULAR GOUT.

The first of these cases occurs in a man named Robert Mascall, 47 years of age. Two years ago he was under my care for a similar disease, since which he has never had a return till now. He labours under one of the most severe forms of the complaint. The gout is principally observed in the joints of the great toes of each foot, and the fourth finger of each hand; but all the other joints are more or less red and swollen, and there is fluctuation in several of them. The pain is intense, and the pulse 126, and compressible—that is, weak. If there had been a strong pulse, I should have thought bleeding necessary; but I ought to mention that it is not good practice to bleed in gout, except under very particular circumstances.

I have said that all the joints of the fingers and toes are red and swollen. How, then, do you distinguish gout from rheumatism? There is a constitutional affection which accompanies gout which does not generally attend rheumatism, though

* Vide MEDICAL GAZETTE, No. 464, p. 119.

sometimes, in the aggravated forms of these diseases, they meet on a confine so exceedingly narrow that it is difficult to separate one disease from the other. It is generally taught in the schools, that gout attacks the smaller rather than the larger articulations; and that it is preceded by constitutional symptoms. This man suffered from derangement of the intestinal canal and the digestive organs. There is generally great distress, loss of appetite, thirst, flatulence, and very low spirits, so that the patient, to use a common expression, is "fit to hang himself," before a paroxysm of the gout comes on. This is not the case in rheumatism; it more immediately follows, in constitutions prone to it, from some exposure to cold. In the case before us these symptoms were present; the disease was preceded by considerable irritation of the stomach and bowels, great vomiting, flatulence, and diarrhoea. Upon the subsidence of these symptoms, the gout appeared in its present aggravated form.

Treatment. — He was ordered to take three grains of calomel, half a grain of opium, and four grains of James's powder, immediately, and to be purged on the following morning with an infusion of senna—half a drachm of vinum colchici, half a scruple of magnesia, and a drachm of tinct. senna; this is a very good purgative medicine for relieving the bowels. Magnesia is an anti-acid, and senna is purging, but why was the colchicum added? This remedy, which is so much cried up in our own time, is as old as the time of Alexander Trallianus, and it appears to exercise almost a magical effect over the disease. It seems that it owes its property to the presence of veratria; and all those roots containing veratria are proved to have a greater or less influence in the cure of the disease. The wine of the root of veratrum, of the root of colchicum, and of the Gratiola officinalis, all contain veratria, and are more or less celebrated for the treatment of gout. This medicine was used by the ancients under the name of *hermodactyls*. Alexander tells us in a few short lines all that we know about it at present:—"The medicine given to a patient labouring under gout causes him almost immediately to walk; but he is more subject to a return of the complaint, at shorter intervals, than before he took the remedy." It was formerly believed that it must purge the patient; that if it did not produce this effect it was of no use; but, given in a larger quantity, it produces a violent degree of hypercatharsis. However, if it be properly managed, no harm appears to arise from it. I have used it in the hospital in rheumatic affections of

the joints for many years, and I never saw an accident with it, or had any reason to suppose that any arose from its exhibition.

The bowels having been acted on by the medicine three times, the fingers being still tense, the urine less high-coloured, the sputa bilious, and the countenance less sallow, resembling the countenance of a person whose digestive organs are much deranged, he was then ordered half a drachm of the wine of the root of colchicum, half a drachm of calcined magnesia, and an ounce and a half of peppermint water, three times in the day; and at night three grains of the acetic extract of colchicum, and five grains of Dover's powders. The object in giving the colchicum here was from its reputation in the treatment of the disease: indeed, it was so great, that by Avicenna it was termed *theriaca articulorum*. A sufficient quantity was given here to make an impression on the disease, and I should say a larger quantity than it is right to begin with in private practice, because persons who live a more confined life than the lower classes, who are much exposed to the elements, will sometimes be greatly affected by such a dose. You should not begin with a larger quantity than a scruple of the wine.

On the 3d of November the heat of the parts was greatly reduced, and he was very much better; but the colchicum was acting violently on the bowels, he was under its influence, and the pulse was a little irregular. He was ordered to take a grain of opium immediately; it was to be repeated at night, and he was to take a rhubarb draught on the following morning. On the 10th the disease was greatly diminished, and the bowels were still open from the colchicum. To-day he can shut his hands; the inflammation is nearly reduced; the joints are still swollen, but he expressed himself as very comfortable. It is impossible to conceive any thing more remarkable than the rapid relief afforded by a single remedy in a disease of such severity as the present case of gout.

General history. — Before proceeding to the next case I will speak of the general history of the disease. The gout, when it occurs in the regular form, generally affects the joints of the great toes, or of the fingers, or of the ankles; it seldom begins in the large joints, and most frequently in the great toe. It is usually preceded by the symptoms which I mentioned, of dyspepsia, heartburn, flatulence, sickness, great indisposition to take food, and great depression of spirits. When a man who has lived what is called *hard*, or, by way of glossing it over, *gaily*, arrives at about the

Idle period of life, he is attacked during night—these symptoms having preceded—by a most violent pain in the joint the great toe; a pain so severe, that those who have suffered it say there is no equal to it in any other disease. The pain goes on increasing till towards the morning, and sometimes it lasts the whole of the following day; and towards the second morning begins to remit, gets better, the patient falls asleep, and has a little repose. The following night the pains begin again; it is lost in the morning; and so it proceeds for several days. Sometimes in the course of the night it changes from the right foot to the left, or *vice versa*, and so it goes on till the fit is over, which generally lasts, in the severe form, several weeks. At first the paroxysms are generally slight; after a time they become more severe; and as the man advances in age they are very severe indeed, lasting much longer each time; or there is a succession of small fits, recurring at very short intervals.

What I have now described is a regular form of the gout; but there are two or three varieties which are more serious. The first, like rheumatism, shifts about: it will leave the foot and attack the hand; it will leave one hand and attack the other; it will attack both hands, and leave them; it will attack both feet, and that in a very short space of time. This is termed *erratic gout*. Sometimes it will leave an extremity suddenly, and attack an internal organ; and this is called *retrocedent gout*. This is a dangerous form of the disease, because it sometimes attacks a vital organ. It not unfrequently happens that where it leaves a part at a distance, the stomach, the heart, or the brain, become affected; or the bowels may be attacked, and there is violent diarrhoea, dysentery, and great pain. The symptoms are sometimes so acute, that they threaten to terminate life. Sometimes sometimes takes place into the skin, and in a short period of time lymph is deposited upon the surface. Sometimes it attacks the viscera of the chest; and inflammation of the lungs may take place upon the cessation of gout in an extremity.

RETROCEDENT GOUT.

We have an instance in the hospital of a retrocession of gout, which is very curious. It occurs in a patient in King's ward, who was admitted under my care about a month ago, with some degree of inflammatory action in the right lung, and a swelling of the legs. He was put under the influence of hydropical medicines—the *pilula hydrargyri*, squills and *italis*, and a nitre draught. He speedily

got well, and was to go out on the Wednesday, when he was attacked suddenly with gout in the hand, affecting the joint of the fore-finger. He appears to have been very subject to the disease, and it appears also, on inquiry, that he has been a person who has lived exceedingly well—better than his circumstances would admit; and he has probably brought himself to his present unfortunate condition by this very means. We asked him what the pain in the joint was like, and he replied, “like the toothache”—a good description of the violent pain which is felt in these cases. His bowels were opened with calomel, followed by senna and vinum colchici, and then he was ordered half a drachm of the wine of the root of colchicum, and half a scruple of magnesia, in camphor mixture; and he took three grains of the acetic extract of colchicum, with five grains of Dover's powders, at bedtime. The urine in this case was scanty and high-coloured, the pulse not above a hundred, not very strong, and occasionally intermittent. This medicine was ordered on the 4th; on the 8th the gout had nearly disappeared: when we saw him yesterday it was entirely gone, but in its place he was attacked with a violent inflammatory affection of the throat, so that he was scarcely able to swallow. On looking into the throat it was of a bright scarlet colour, very much like florid erysipelas; and there was some swelling of the right tonsil, attended with a greater degree of pain, and a more increased secretion from the membrane, than usually takes place in cynanche tonsillaris. Here is an instance of the transference of gout. In private life I have heard of a case which was exactly the reverse of this. A physician of considerable eminence was attacked some three or four years ago, after exposure to a draught of cold air, with what appeared to be cynanche tonsillaris. It was so severe that it prevented him from swallowing for several days, and he began to fear that he should be starved to death—precisely like our friend up stairs, who expressed himself alarmed on that account. He continued in great agony for several days, when the affection suddenly disappeared, and he called for some tea and toast, which he took with great relish; and within a short space of time, I think within an hour, the gout appeared in the foot. Here was an instance where the gout first attacked the throat, and then the foot; exactly the converse of the case under consideration.

Treatment.—The great object in this case is to diminish the inflammatory action going on in the throat, and to bring the gout back to the extremity. Three

grains of calomel, and half a grain of powdered opium, were put on his tongue every six hours. He was ordered a mustard poultice to surround the throat, which is sometimes effectual in relieving the attack; his feet were put into hot water, and to-day he is a good deal better. He sleeps more easily, the throat is less inflamed, there is less secretion; but the mustard cataplasm has not had the effect desired, and I have ordered a blister behind each ear. The mouth is not sore. It is possible that, by treating the disease of the throat itself as an inflammatory disease, we may get rid of the whole attack, or in the course of another day and a night the gout will probably appear in the foot, to the great relief of the inflammation at a distance. Here, then, I can shew you, what is not often seen in a hospital, a case of retrocedent gout.

ATONIC GOUT.

There is yet a third case of this disease in the house, occurring in a man of the name of Henry Elliott, in Fuller's Ward, who has been subject to slight and frequent attacks of gout for many years. At present he has slight pains in the knee, with much sensation of weakness; the pulse 100 and weak; tongue clean; the attack preceded by loss of appetite and lowness of spirits.

This is not like the other cases; there is no inflammation present; and it more resembles what is termed *atonic* gout. Where a person has been subject to fits of the gout, and it is not manifest upon the extremities, it not unfrequently happens that the constitution appears to suffer very materially. Without any obvious reason the patient declines in health and strength, the limbs become weak, the digestive powers are impaired; and this is termed *atonic* gout.

Treatment.—The best way of treating this complaint is, to endeavour to remedy the condition of the digestive organs, and let the gout alone; let the patient gain strength, and recover from the weakness of the limbs.

A great many remedies have been prescribed for keeping off the gout. A great many persons in private life, if their bowels are confined, take every morning 3 or 4 grains of rhubarb, and double the quantity of magnesia, and they will continue this for weeks together. By regulating the digestive organs, getting rid of the acid secretion when it is formed, and inducing a habit which prevents its formation, many persons keep off the gout. Where the bowels are affected with looseness, as sometimes happens, it is better to take the same quantity of rhubarb, with double the

quantity of carbonate of soda. The latter remedy, not for the cure, but for the keeping off of gout, has been much recommended; and there was an idea that it would prevent it to all eternity. Persons used to be seen at dinner, if you watched them closely, screwing out little bits of paper containing 5 or 10 grains of carbonate of soda, which they emptied into a glass of white wine, believing it would act as a prophylactic. I believe that it is a good mode of correcting acidity in the digestive organs, but I do not hear that gout is less frequently met with than before. Unless at the time of taking the soda the dinner could be dispensed with, I doubt whether the gout could be prevented by it; and I think that persons might dispense with the soda, if they would at the same time dispense with the dinner.

I ordered for this patient 6 grains of rhubarb, half a scruple of carbonate of soda, 2 grains of P. Cinnamom, and 3 grains of Pulv. Rad. Calumbæ, to be taken in a glass of water every morning. I believe that, with a well-regulated diet, this remedy has power to cure these trifling cases of gout.

What are we to say, suppose the gout leaves one extremity and attacks a vital part—the lungs or the brain? Humoral pathologists, having an idea that gout must appear on the extremities, and that if it did not, the patient was likely to die, were of opinion that purging or bleeding, to disturb the concoction of morbid matter, was bad. What was the consequence? There is a general expression that bleeding in a gouty constitution is contra-indicated. Had it been any other disease than gout, I should have taken blood the other day, but I knew that the patient would be relieved by other remedies which have the effect of relieving gout itself. Nevertheless, one of the most staunch supporters for not interfering with the humours—Sydenham—says that there can be no doubt that if the disease recede from an extremity, and attack a vital part, it is to be treated like all other inflammations. He illustrates this position by referring to the lungs, and says that the complaint will sometimes leave an extremity, and attack the lungs, in which case it is to be treated as a true peripneumonia. He applies the same reasoning to the head. I think that I should be treating you very ill if I were to leave an impression on your minds, that in the case of the transference of gout to the brain or lungs, you were not to bleed, seeking at the same time, as much as possible, to bring back the gout to the feet, by the application to them of a mustard cataplasm, or friction, or warm remedies of that description.

Persons who recover should always have recourse to bitter medicines, and one of the most famous was Portland powder, a combination of bitters mentioned as far back as the time of Cælius Aurelianus. So do we move in this kind of cycle; there is constantly coming to the top of the wheel what was at the bottom; and we employ what our predecessors used before us, and with the same benefit. Portland powder was given in great abundance to persons who suffered from the gout, with a view of correcting the digestive organs. The powder which I gave to Elliott was upon the same principle.

I have mentioned the phenomena of the fit; you have seen the manner in which it is to be treated, the danger which arises from retrocession, and how that is to be remedied.

We will now speak of some of the alleviating circumstances. The first man had a tepid spirituous lotion applied to his hands. You must be careful how you apply cold to the hands: the application of cold water has been recommended by some authors who differ from the rest of the world. A spirituous tepid lotion, however, will sometimes relieve the pain immediately; and where it can be borne without pain, it should never be omitted. Dr. Scudamore has written an excellent work on gout, which you may read; and he lays great stress on the comfort to be derived from the use of a spirituous lotion. In the present case heat was abstracted, and there was a great relief of the painful affection. By the use of these remedies you will sometimes have no gout appear, but there will be gout at a distance—gout in the muscles of the back; and this will be relieved by taking three grains of the acetic extract of colchicum, with five grains of Dover's powders, not during the day, but at night.

There has been a great dispute in the profession, as to whether we should use the wine from the seeds or from the root. I always employ the latter, because it is the most effectual; and I am told that a preparation of wine from the seeds is of far less strength. However, if the wine from the root makes the patient sick, you may try the wine from the seeds. You must remember that this is a matter of experience, and not of theory, for it happens that one kind will agree, while another fails. Thus in the case of Dodson, who suffered from a severe affection of the joints, he was ordered three grains of the acetic extract of colchicum twice a day; it disagreed with his stomach, and produced vomiting, and was attended with all the bad consequences resulting from it. I ordered him the inspissated juice twice a day, in a quantity equal to three grains of

the acetic extract, and he was able to bear it. I saw a case in private practice, in which I ordered a grain of the inspissated juice, with opium; it produced no effect on the disease, but disagreed with the stomach. I think I ordered three grains of the acetic extract, and the converse of what occurred up stairs took place; the acetic extract succeeded where the inspissated juice failed. The same thing will occur with all the various preparations of this medicine with which I am acquainted. You are not to suppose that because one sort fails, therefore colchicum disagrees with the constitution; on the contrary, if you vary it, it will perhaps be found exceedingly serviceable. There is an idea that colchicum is apt to prepare the patient for more frequent attacks of the gout. In hospital practice the disease is rarely to be seen, but in these gouty affections of the joints, the cure is as perfect as in any other complaint. I have seen the worst effusion taking place—every joint of the body full of the disease. I have kept the patient some time in the house, and there has been no tendency to a return of the disease. A great deal of blame which is heaped upon medicines which relieve the gout, and so immediately relieve it that nothing can approach to the advantage derived from them, is rather to be attributed to the conduct of the individual. The moment that there is a relief from the pain, the same course of life is pursued which led to the preceding attack; and it is probable that the recurrence of the affection is rather to be attributed to the life led, and especially when there is an idea of immunity from the disease, than to the fact of the complaint having a tendency to domicile in the system, or to any other theoretical idea.

ŒDEMATOUS GOUT.

There is another form of gout, but of which we have not a specimen in the hospital. It is termed *œdematous* gout—that is to say, the hand or the foot pits on pressure; there is little distinct pain, and the constitution is very languid. This form is dangerous where it is transferred. I have seen one or two cases in private practice, and it is very amenable to the usual doses of colchicum. I saw a gentleman who came from abroad, and who told me that whenever he was attacked with the disease, he cut a hole in his shoe, but his toe was not very painful unless he walked upon it. He did not feel it at other times. He had been in the habit of taking 20 drops of vinum colchici when the disease came on, and it always cured him in two or three days. At Paris, he got what he thought was a bad kind, because it disagreed with him. I recom-

mended the acetic extract, and it dispersed it in a day or two. You see the extraordinary power which this remedy has. There is no doubt that when the patient is well, it is a good plan to give one or two doses of calomel, and endeavour to improve the secretions of the liver. If the bowels are disordered, it is generally best to give 3 or 4 grains of blue-pill at night, and sulphate of magnesia in mint-water, in the morning. In this way you may entirely establish the patient's health. We live in a world where it is all very well to say that persons should live abstemiously, but it is impossible to induce your patients to do it; if you told them that they must, they would not obey you. The next best thing is to say what may be done. This will depend upon the habits of the individual. It has been considered that Spanish wine is the best for patients to take, because it contains the least acid. Claret and Moselle contain a great quantity of acid, and are very apt to bring on a fit of the gout. It is said that there is more gout in one parish in London, than in all Bourdeaux and Germany, where the wines are made. But the question is, what is best for the disease when established. Sherry-and-water is the best you can recommend; or two table-spoonsful of brandy in soda water, which is better still. Vegetables should not be allowed; still it does every now and then occur, that after persons have left off vegetables for a great length of time, and the gout has not diminished, that returning to well-boiled vegetables has been attended with advantage. Probably the benefit arises from the abstinence from meat; and if persons would abstain altogether, no doubt they might be cured. I recommend you to read Sydenham, who has some curious cases. He records an instance of one man who lived on milk, with which he took a slice of bread for a year, and he got rid of the complaint. He could not be persuaded to continue it longer. I know of a very curious private case. The patient had the good sense to abstain from good living altogether, and he entirely recovered, and got rid of the disposition to gout. When a person has once incurred the habit of hard living, it would appear that the constitution is brought into that state in which the food cannot be digested without a certain portion of stimuli, and in general animal food is to be preferred, and a warm wine in moderation, mixed with water, rather than acid wines or vegetables.

I have no farther remarks to offer at present on these cases, but I beg that you will watch them, for they are very interesting.

ST. BARTHOLOMEW'S HOSPITAL.

Stricture—Abscess in Perineum and Prostate Gland—Effusion of Urine—Death.

EDWARD WALKER, aged 59, admitted into St. Bartholomew's Hospital, under the care of Mr. Earle, November 5, 1836. He states that he has suffered from stricture in the urethra for thirty years; that he has had difficulty in making water during the same period, and that this difficulty was greatly increased on last Thursday week (October 6th); in consequence of which he applied to a medical gentleman, who made an attempt to pass an instrument for him, but without success: it did not reach the bladder, and he bled very much after the operation.

On the evening of the same day, he suffered great pain in the perineum, and could only pass a small quantity of water. He did not seek medical advice from this time until Thursday, November 3d (a week), two days previous to his admission, when another unsuccessful attempt was made to introduce an instrument, after which only a very few drops of urine followed.

Saturday, Nov. 5th, 9 o'clock A.M.—He now states that he has not made water for a week. There is considerable fulness of the perineum, with great pain of that part, and some pain of the scrotum. His countenance is expressive of great anxiety. Tongue covered with a dark brown dry fur; pulse quick, and small. An attempt was made to introduce a silver catheter, which came away much blackened and discoloured, and about eight ounces of extremely foetid urine followed the removal of the instrument. He was placed in a warm-bath; in which he remained about twenty minutes, and obtained great relief. Mr. Earle saw him about one o'clock in the afternoon, and, after unsuccessfully attempting to introduce a catheter, he cut down upon the urethra through the perineum, with a double-edged scalpel, laying open the canal immediately behind the bulb. Some of the same foetid urine slowly escaped. On attempting to pass a catheter through the wound into the bladder; it passed evidently out of the canal of the urethra into a boggy undefined space, having bristles extending across it in all directions, and which gave the sensation of a cavity in which there was breaking down of cellular structure. With much difficulty, a gum-elastic catheter, without a stilette, was introduced into the bladder. This was retained in position by proper bandages. He takes a saline mixture with antimony.

7 P.M.—He expresses himself much relieved by the operation; healthy urine

passes freely through the catheter; he complains of no pain; tongue moister, but still much furred.

6th.—Has slept well (the first sleep he has had for some days past); urine passes freely, both through and at the sides of the catheter, but he complains now of great pain in the scrotum and left groin. Fomentations ordered to these parts. Tongue remains as yesterday, as does the pulse. Bowels are freely opened.

7th.—Has had rigors at intervals, though he has continually dozed since yesterday. The catheter is removed from the wound, as the urine flows freely past it; the pain in the scrotum and groin has much subsided, though the scrotum is greatly enlarged and livid. A large diffused swelling, with considerable redness of the integuments covering it, was observed in the left lumbar region, extending down to the brim of the pelvis. A puncture was made into this with a lancet, and some bloody urine escaped; and minute punctures were also made into the scrotum. He was ordered to discontinue the antimony, the action of which was transferred from the skin to the bowels. Wine and brandy were ordered to be administered frequently, and fomentations to be applied to the loins and scrotum.

8th.—Urine continues to escape through the wounds in the perineum and loins. He lies in a comatose state, and is rapidly sinking.

He died on Wednesday the 9th, having been quite insensible during the last twenty-four hours.

On examination after death, the urine was found to have completely infiltrated the cellular tissue of the perineum and scrotum, the left groin, and to have extended upwards to the loins, and even to the axilla, on that side; but no urine was effused into the cavity of the abdomen or pelvis. The bladder was much thickened, and the mucous membrane in an ulcerated state. The prostate gland was slightly enlarged, with an abscess in its substance. The urethra was very much diseased, the first four inches being the only part assuming at all a healthy appearance. There was great difficulty in following even the track of the remaining part, which appeared to have given way about the membranous or muscular portion. Opposite to this spot there existed an abscess in the perineum, communicating with the urethra, and also with that in the prostate gland. It was also evident that several false passages had existed, one of which, after pursuing a course of about two inches, perforated the urethra again. The kidneys were healthy, but the ureters much dilated.

It would have been exceedingly interesting to have discovered whether the urethra was ruptured primarily, in consequence of ulceration commencing within its canal, or whether this was secondary to the prostatic and perineal abscesses. From the condition of the patient when he entered the hospital, and state of the parts after death, the solution of this difficulty was rendered impossible.

THE NERVES AND MUSCLES OF THE EYE-BALL.

To the Editor of the Medical Gazette.

SIR,

IN justice to Sir Charles Bell, I have to thank Mr. Shaw for shewing that I ought to have coupled the name of that anatomist with that of Bojanus, as having, amongst modern authors, alluded to the distribution of the sixth nerve to the suspensory muscle of the eye of the lower animals. Although I have perused "The Nervous System" of that author—I will not say "with the greatest attention," but certainly with as much as I am capable of—yet, upon the occasion of my attention being lately directed to this subject by the publication of the observations of Mr. Walker, not having Sir Charles's large work by me, I contented myself with referring to the original papers published in the Philosophical Transactions, knowing that nothing material was afterwards added to the papers on *this* subject. I now find, upon comparing the two works, that the passage alluded to by Mr. Shaw, which I had overlooked, is about the only one added to the papers as originally published. I do not fear being charged with any culpable neglect of the sources of information, in omitting to refer to the "Anatomy and Physiology of the Human Body," when desirous of studying the original observations and theories of the author, of which, in this work, he himself observes, that "the substance" only is "introduced in their proper places*."

I cannot but regret that, in his injudicious zeal to advocate the claims of Sir Charles Bell, Mr. Shaw should have allowed himself to pen a communication which is so evidently wanting in good feeling, and which contains such numerous perversions of the statements contained in my communication.

* Preface to the Anatomy and Physiology of the Human Body, by John and Charles Bell. 7th edition, p. 12.

Lest, however, this angry piece of criticism should mislead any of the readers of the *MEDICAL GAZETTE*, I will make a few remarks upon the general question. I had thought that the object of my communication was sufficiently evident; it was neither that of refuting, nor of advocating, any theory or theories relative to the functions of the muscles and nerves of the eye-ball. If it had been intended as an attempt at the former, I should certainly have entered at length into the consideration of the two theories to which I briefly alluded—those of Sir Charles Bell and Mr. Mayo. Neither did I attempt to advocate the theory of Messrs. Hunt and Walker: my simple object was that of calling the attention of those interested in these inquiries to a single fact bearing upon the question—a fact certainly not generally known to anatomists, and not even alluded to in the various professed treatises on comparative anatomy: I allude to the distribution of the sixth nerve to the suspensory muscle. In reference to the function of this muscle, I stated that “I inclined to believe” that it was a suspensor rather than a retractor of the globe, admitting, however, that it might be both. This opinion I hold, not only in common with Willis (whose theory, stated in rather broad terms, is quite caricatured by Mr. Shaw), but also with Briggs, Munro*, Grant†, and Porterfield‡. Cuvier, Elliotson, and Owen, would also appear to have the same view of the function of this muscle; for they all denominate it not retractor, but *suspensorius oculi*. Some of these names may, perhaps, be sufficiently modern to be “authorities in physiology,” even with Mr. Shaw, who, one is almost inclined to think, receives nothing as authority upon this subject that was written prior to 1823. The view of the function to which I merely stated “that I inclined,”—though Mr. Shaw speaks of my giving it my “especial approbation,” and even of my “admiration” for it—I endeavoured to support by an argument founded upon a fact in the anatomy not even alluded to by Willis; and for which, as an original observation, I might, perhaps, “claim some credit.” The very disproportionate nervous supply of the suspensory muscle (compared with the abductor as one to four), is a fact, the importance of which I should suspect will not be denied; but the reference to it, and its application to

the view taken of the function, is totally passed over by Mr. Shaw.

I look upon the theory of Mr. Hunt and Mr. Walker to be one referring simply to the *primary* functions of the muscles of the eye-ball, and to their mutual connexion; and therefore to be a theory not necessarily inconsistent with some other views relative to their *secondary* and *related* functions. Of this character, I think it not unlikely, are some of the views of Sir Charles Bell, and perhaps some of those in particular which relate to the mechanism of the third eyelid of the mammalia, a knowledge of the existence of which, Mr. Shaw, in the most considerate manner, appears disposed to deny to me.

The “original theory” to which Mr. Shaw alludes, as explaining the reason “why the sixth nerve in man should supply the abducens muscle of the eye exclusively,” we find that Sir C. Bell merely speaks of as “a surmise,” and candidly says that “in accounting for a certain peculiarity in the action of the sixth nerve, we have not a very satisfactory reason why it should be solitary in its origin and course*.” Upon Sir C. Bell’s own shewing, therefore, I come to almost precisely the same conclusion as to the defective character of his theory of the nerves and muscles of the eye-ball, as that which I took in my former communication.

There are, however, I believe, many points connected with this subject, when taken in all its bearings, which yet remain to be made out, and that especially as refers to the comparative anatomy; and some of these I hope to have the leisure to prosecute, and would invite others to enter into the same field of inquiry. It is, I believe, in this way only that we shall be enabled to arrive at a satisfactory conclusion respecting a subject which has been more or less unsuccessfully agitated, almost ever since anatomy has become a distinct science.—I am, sir,

Yours very respectfully,

JOHN THURNAM.

Westminster Hospital,
Nov. 23, 1836.

UNION SURGEONS AND THEIR PAUPER PATIENTS.

To the Editor of the Medical Gazette.

SIR,

YOUR correspondent, “E. C. T.,” wishes to be informed if I consider 11,800 persons to be the *pauper population* of the parishes

* Munro’s Comparative Anatomy.

† Grant’s Outlines of Comparative Anatomy, p. 272.

‡ Porterfield on the Eye, 1759, vol. i. p. 92. This author thinks that the seventh muscle may also act in such a way as to prove subsidiary to the straight muscles.

* Nervous System, p. 215.

gdom, have been long engaged in out pauper lists for the guidance of surgeons?—"The Union consists of the following parishes: Leighton Buzzington, Eggington, &c. &c. &c. comprises a population of 11,800 persons. The gentleman appointed will be bound to devote his whole time to the duties of his situation, &c. &c."

"Sir, why is the gross amount of the salary named to a man who is to devote his whole time and attention to the duties of his situation? What are the opulent classes to be expected to do nothing, except to tantalize him. They may just as well invite a man to a banquet or venison feast, at which all the distinguished characters of the county are to be expected, and, when he arrives, place a side-table, allow no one to speak to him, and feed him with cold potatoes. This is the point. "E. T. C." has not fame with the amount of the pauper population; a matter, let me tell him, not easily decided, and liable to perpetual variation. However, I shall probably be very far wrong if I suppose it at present comprising more than one-third of the population, or 4000 individuals. I will maintain my argument, that no one practitioner could properly attend the pauper population in that number, scattered over fifteen country parishes. "E. C. T."

That "all country practitioners are to the same discomforts as the Union Surgeon." That all country practices are attended with fatigue and inconvenience, is universally acknowledged; but there are very few country practitioners, in extensive business, who attempt to throw the whole burden upon their own shoulders; there is either a partner, a well-qualified assistant, or an apprentice—very rarely all three, who divide the labours

and independent labourers, as they are called (deliver me from such independence!). According to the old plan, the surgeon was engaged at a given salary (I am sorry to say, nothing like a proper remuneration for his services), to attend all the poor on every occasion of illness, midwifery generally excepted; nor was he very scrupulous as to who he admitted as a parish patient. Many a poor fellow, struggling hard to bring up a family in a respectable manner, has received medical relief for himself, his wife, and children, without a charge; the parish surgeon scorning to present a bill to a hard-working man, who could not afford to remunerate him properly: but according to the present system, none but the absolute pauper, whose name, age, occupation, and disease, are to be inserted in a weekly list, are to be considered entitled to medical relief, and the member of the Royal College of Surgeons is to be screwed down to the lowest possible farthing for attending them; and, by way of increasing his paltry pittance of a salary, is required to submit to the degradation of receiving halfpence squeezed from poor men's children, to remunerate him for his attendance on what are absurdly called independent labourers, subscribing to medical clubs. This, sir, is really scandalous. How is it possible for a poor man to afford any contribution to a medical club, whose wages amount to no more than seven or eight shillings a week, which is the average rate of wages in the agricultural neighbourhood in which I have resided many years? This poor fellow, be it remembered, is compelled to pay to the parish rates: if he can keep his wife and family from absolute starvation, it is in my opinion wonderful

suitably clothed, lest they fall into disease and become unable to work. Let the scale of diet be taken, not from the low diet of an hospital, but from the scale fixed for healthy soldiers and sailors. Work them hard; feed them well; and put them, as quickly as possible, into situations where they may support themselves. As for your independent labourers—men who are struggling hard for a livelihood—encourage them, assist them, and, in particular, give them medical relief without a charge.

If you deprive the poor of a proper quantity of nourishing food, and suitable clothing—for this I consider equally necessary—what have you to expect? That the children of the present day will grow up lax, feeble, dispirited, scrofulous wretches; and that the next generation will inherit, in a still greater degree, the debilitated constitutions of their parents. Where, then, shall we seek for the true John Bull? Where shall we find those brave determined characters to man our fleets and our armies—such men as I remember some five-and-twenty or thirty years ago, when Nelson, Collingwood, and Pellew, fought and conquered; when Wellington led his brave army through Spain and Portugal, and finally terminated the war in the ever-memorable and hard-fought field of Waterloo! The crews of those ships—the privates of those regiments—were men worthy the name of Britons. But the next time his Majesty's Ministers find it necessary to wage war against a foreign power, if the present poor law system be continued—alas! for our fleets and our armies: no longer must we sing “*Britannia rule the waves.*” But I hope the matter will be reconsidered, and that the British flag will, for many ages to come, be seen to float triumphant, not only on our own seas, but every sea, even to the utmost boundaries of the earth.

I am, sir,
Your obedient servant,
AN OLD NAVY SURGEON.

Nov. 15. 1836.

**THE PRIZE EXAMINATION AT
APOTHECARIES' HALL.**

MR. TEGETMEIR, who obtained the second prize, (not Teggemeir, as printed in our last), has written to say that the account we gave of the examination being partly oral, was incorrect. The statement of the examiner himself, we presume, should be conclusive. At the meeting of the Court, Mr. Ward said that on previous years the examination had been written, and *virâ voce*; but that the adjudication was founded on the written answers. This year, however, he (Mr. Ward) had combined both; that is, the

determination of the names and natural families of certain plants (constituting the *virâ voce* examination) was proposed to the candidates at the same time that the written questions were put.

We have only one slight correction of our report to make—namely, that the lowest of the five first competitors had the number of marks assigned to the third.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

By WILLIAM CUMMIN, M.D.

LECTURE X.

The subject of Rape medico-legally considered—What is meant by the term in legal acceptation—Opinions of the Judges—Case of the convict Williams—Physical proofs of Rape—The sexual organs in the Virgin—Ambiguity of the signs of Defloration—Too little or too much proof—Evidence of emission ought to be sought for—Seminal spots; their physical and chemical characters—Spermatic animalcules described.

We shall next proceed to consider those abuses of the sexual functions which are connected with the commission of certain heinous crimes.

Fornication.—"In all civilized countries," says Dr. Percival, "the honour and chastity of the female sex are guarded from violence by the severest sanctions of law. And this protection is at once humane, just, and necessary to social morality. It is consonant to humanity that weakness should be secured against the attacks of brutal strength: it is just that the most sacred of all personal property should be preserved from invasion: and it is essential to morality that licentious passion should be restrained, that modesty should not be wounded, nor the mind contaminated—in some instances, before it is capable of forming adequate conceptions of right and wrong."

The medico-legal consideration of outrages on chastity comprehends the cognizance of a variety of circumstances

more or less indicative of violence offered to individuals of the other sex. The inquiry submitted to the professional examiner may either relate to the proofs of a capital crime, or those of a high misdemeanor; and it generally happens that the indictment is preferred, either for the completion of the offence—actual rape—or for an assault with intent to commit that crime,—and this according to the amount of evidence which the medico-legal inspector may be able to adduce.

Legal distinctions as to what is meant by Rape.—But let us determine, in the first place, what is meant by the law authorities, when they speak of the crime of rape. The ordinary definition seems clear; yet it is far from being so explicit as not to require further explanation. Blackstone says it is "the carnal knowledge of a woman forcibly and against her will;" but then, what are we to understand by "carnal knowledge?" for there are discrepancies on the point in the records of our jurisprudence. In common law, and in accordance with the decisions of many able and learned judges, emission has been held essential to the completion of the crime; and in order to conviction, there should always be either positive proof of that fact, or it should be inferential with a high degree of probability. The statute law, however, as enacted a few years since, seems to make carnal knowledge consist in penetration merely.

These are the words of the act [9 Geo. IV. c. 31. s. 18.]—"And whereas upon trials for the crimes of buggery and of rape, and of carnally abusing girls under the respective ages hereinbefore mentioned (viz. ten and twelve), offenders frequently escape by reason of the difficulty of the proof which has been required of the completion of those several crimes; for remedy thereof, be it enacted, that it shall not be necessary, in any of those cases, to prove the actual emission of seed, in order to constitute a carnal knowledge but that the carnal

knowledge shall be deemed complete upon proof of penetration only."

Question of penetration.—Here you will probably say that the matter is perfectly clear; there can be no more difficulty; the law is well defined; and nobody can mistake the meaning of the statute. But not exactly so: the interpretation of acts of parliament is not so very simple as many people suppose. A point was made by some of the judges, not long after the promulgation of the statute just quoted, involving rather an intricate question. It was assumed that the statute could not be at variance with the common law, and that however the *evidence* requisite in proof of carnal knowledge might be altered, the *nature* of the crime remained the same. It was further argued, that the very wording of the statute confirmed this opinion; for it spoke of the *difficulty* of obtaining proof of emission, and provided that it should therefore be dispensed with, as not absolutely essential. Hence it was held that if emission could be negatived, or, in other words, if it could be proved on the part of the accused that there was no emission, the capital indictment could not stand.

But perhaps I had better read for you an abstract of a judge's charge, in which this view of the meaning of the statute is laid down. The case was a trial for rape (Carlisle Spring Assizes, 1832), where the prosecutrix proved *penetration*, and that *her clothes were wet*. Mr. Justice Alderson thus addressed the jury: "You must be satisfied that the prisoner penetrated her private parts with his: if you are satisfied of that, I shall submit to your consideration another question, viz. according to law it is established beyond all doubt, that on proof of penetration, a jury may infer completion of the offence—the offence still consisting of penetration and emission. But a doubt has arisen upon a late act of parliament, whether where no emission has taken place, the offence is complete by penetration only. I have no doubt, however, that it is for you, if you are of opinion that there has been penetration, to presume emission, unless the contrary is proved; and it lies on the prisoner to show that emission did not take place. If you are satisfied of penetration, but that no emission did take place, I shall reserve the question for the judges; but if you are convinced of the penetration, and in doubt or ignorance whether emission took place, I am clear you ought to find the prisoner guilty."

The jury did not trouble his Lordship to refer to the judges on this occasion: they acquitted the prisoner. But at the same assizes (Spring, 1832) for Worcester, a case was tried, which brought the question to an issue.

John Cox was convicted of rape, upon the following finding of the jury;—"We are of opinion that *penetration* took place, and we are of opinion that *no emission* took place." Whereupon the judge passed sentence on the prisoner, but granted a respite, in order that the opinion of the judges might in the meantime be taken. In the next (Easter) term, the judges were accordingly consulted, when they gave it as their unanimous opinion that the conviction was right. Sir Gregory Lewin, however (from whose excellent "Report of Crown Cases on the Northern Circuit" the foregoing particulars have been borrowed), adds, that "the case was not argued before the judges by counsel:" so that we must not be too sure that the point is definitively settled yet.

But let us suppose—as we certainly have a right to do—that the meaning of "carnal knowledge" has been defined—that it signifies "penetration;" is there nothing further to be explained?—are the authorities all agreed as to what is meant by the latter term? It would appear not.

Some modern cases—among them, that of Cox, just now quoted—would lead us to believe that sufficient proof of penetration might be obtained, "although the hymen were not broken, and the vagina were found so small that even a finger could not be introduced:" in fact, the statute has been interpreted in its obvious sense, as implying that *any* introduction of the male parts within the labia externa constituted penetration. But a remarkable case, which attracted much public attention about two years ago—that of the convict Williams, who was sentenced to death for a rape committed on a child of eight or nine years of age—seems to have shaken the commonly received sense of the term, if not to have in a great measure stultified the law. It was urged by a medical man, who took a very active part in inquiring into the circumstances of the case, and who may be said to have saved the prisoner's life, that *legal* grounds for the conviction were wanting—that penetration was not proved; and, indeed, that from the relative condition of the parties—a grown man and a child under puberty—the fact was physically impossible. He maintained that there was no proof (as, indeed, there was not) that the hymen had been ruptured, and thence argued that there was no evidence of penetration: in support of which view, he adduced the authority of certain anatomists, who held that all exterior to the hymen is exterior to the body—that membrane forming the natural barrier through which alone admission could be obtained into the sexual parts. He further offered to prove that the male organ

of the adult could not be introduced into the undeveloped vagina of the impuberous female. The Secretary of State, to whom these representations were made, was staggered by their force, or at least satisfied that sufficient care had not been taken to procure evidence of penetration; a respite was accordingly granted, and ultimately, it being found that however unquestionable was the moral guilt of the prisoner (the crime, in fact, was committed with circumstances of gross atrocity), the legal proof required by the statute was not had, —a commutation of the sentence was accorded.

Now if this case were allowed to form a precedent, it is evident that the present law of rape would, in a large proportion of cases, become a dead letter. It would be frequently impossible to convict a criminal who had committed the grossest outrage on a female child, and the proof of rape effected on adults would be rendered in the highest degree difficult: the ends of justice would be defeated. But some late convictions for rape on infants, show that no such precedent has been established: and notwithstanding the dissentient opinions of one or two of the judges—Baron Gurney, for example, and Mr. Justice Taunton—the law is likely to be henceforth interpreted in its proper and obvious signification.

It must be admitted that the point made by the gentleman referred to was ingenious; but I apprehend that the great body of anatomists would refuse their assent to the doctrine which he maintained—that the external sexual organs of the female, from the hymen outwards, were only the exterior of the body: for, independently of the difference of integument observed on the outer and inner portions of the external labia, it is contrary to all usage to assert that the labia interna, prepuce, clitoris, &c. are external parts. Besides, in the natural condition of the female organs, the opposite portions of the pudenda lie in contact; and, in short, it were perhaps as rational to say that a catheter introduced into the bladder was not really within the body, as that penetration would not be effected unless the actual vagina were invaded.

Physical proofs of Rape.

Evidence of penetration.—We have next to consider what are the proofs of penetration. These may vary, from the most slight to the most palpable. If we have no opportunity of observing them early, they may be greatly modified, if not entirely obliterated. But in general, in cases of actual rape, there will be found sufficient indicia of violence: the brutality of the offender will leave its traces; and the probability is, that, in the actual state of the law, mere

penetration being as punishable as the most perfect completion of the carnal knowledge, the guilty party, who may be aware of that fact, will not be careful in attempting to save appearances. We may, therefore, when called to examine the person of a complainant a few hours after the alleged commission of the offence, expect to find such marks and tokens as may warrant our judgment respecting the true state of the case.

Defloration.—It mostly happens that the females who suffer sexual violence, constituting rape, are young, unmarried, or persons who have not had sexual intercourse before. The signs, therefore, resolve themselves into those of forcible defloration. Now, in order to be able to appreciate the indicia of defloration, or deprivation of virginity, it is necessary that we should be acquainted with the natural uninjured state of the sexual parts in the young female.

The female organs in their uninjured state.—The vulva is described, by Maygrier, as comprising the mons veneris, the labia majora and minora, the vestibule, the clitoris, the urethra, the hymen, the carunculæ myrtiformes, the fourchette, the perineum, and the entrance of the vagina. Some of these parts will need to be specially noticed.

The mons veneris is the prominence in front of the os pubis, composed chiefly of a quantity of fatty cellular substance. It begins, at puberty, to be furnished with hair, which is more or less abundant, according to the age, constitution, and habits of the party.

The labia majora, or externa, extend from the mons veneris to the perineum. They are large in women of full habit. Externally, they are covered with integument, which is the continuation of that of the thighs, and contains a large supply of sebaceous follicles. Their internal surface is of a reddish colour, smooth, and consisting of mucous membrane; and the opposite sides are in contact, in their undisturbed condition.

The labia minora, or nymphæ, are two membranous folds, erectile, and of a bright red colour, commencing from the prepuce of the clitoris, and broader in the middle than at the extremities. They are very large in female children at birth, but of a moderate size in the adult. It is to be observed, however, that the size of the nymphæ varies very considerably, according to the age of the individual, the country she belongs to, and the maladies that may have affected the part. It has been sometimes necessary to remove them with the knife; nor is the operation usually attended with any unpleasant consequences.

Between the clitoris and the orifice of the urethra, and bounded laterally by the nymphæ, is a triangular space, somewhat

depressed, and, in uncleanly persons, containing a quantity of sebaceous matter. This is the *vestibule*.

The *clitoris* is an elongated tubercular body, lying within the upper commissure of the nymphæ, and commonly concealed by the labia externa. It is of different size in different individuals. In the well-formed virgin it is small. But we have seen, in a former lecture, that the part is sometimes so large, in certain females, as to assume the appearance of a penis. It is composed of an imperforate glans, encircled with a membranous fold, which forms for it a kind of prepuce,—of a cavernous body, fixed by two roots to the descending branches of the pubis, and connected with the symphysis by a sort of suspensory ligament.

A little papular prominence containing an aperture is observed at the base of the vestibule. This is the urethral orifice. The urethra itself is capacious, but not much above an inch long.

The *hymen* is a membranous fold, differing in size and shape in different females, and formed of the mucous membrane of the vulva, just as it dips into the vagina. It is situated at the posterior and lateral parts of the orifice of the vagina, so as to close the passage more or less completely. In general, the thickness of the membrane is inconsiderable; but occasionally it is both considerably thick and tough. With regard to form, it is most frequently semilunar, sometimes elliptical transversely, or nearly circular, with a central aperture. In some rare cases it is without any aperture: it is imperforate; when it prevents the menstrual discharge, and must affect the health. An operation is, under such circumstances, requisite.

Some eminent accoucheurs inform us of a remarkable fact, that they have sometimes found the hymen so strong and unyielding as to interfere with the progress of a labour; in which case they have been obliged to free the passage by an incision. The fact is well worthy our attention, as medical jurists, since it shows that not only sexual intercourse, but impregnation, may be effected without any rupture of the hymen. On the other hand, the absence of this membrane, in the opinion of many, warrants the supposition that it was destroyed by some mechanical means; but it is considered that some very slight accident may lead to it: it may have occurred in childhood, for nurses sometimes, in rubbing dry the sexual parts, may break the hymen; or inflammation with ulceration may supervene, and obliterate that emblem of virginity—which may thus be too hastily presumed to have been lost, when it happens simply not to be present.

Caruncule myrtiformes is the name given

to certain little reddish tubercles, of different shapes, round or flat, which are formed, as most authors believe, of the debris of the hymen, but, as Beclard has endeavoured to show, of the mucous membrane which is puckered or gathered in those parts. If this latter opinion were correct, carunculæ ought sometimes to be found contemporaneous with and previous to rupture of the hymen; they are, however, rarely, if ever, found, save in the absence of that membrane. Their number varies from two to five or six, and their colour and consistence depend on the constitution of the female: they may be of a bright scarlet hue, or they may be pale and livid; they may be firm, or soft and yielding.

The *fossa naticularis* is a little depressed space, lying between the lower part of the orifice of the vagina, and the posterior commissure of the labia externa, which latter part is often denominated the *fourchette*. And lastly, the *perineum* is the space lying between the fourchette and the anus; it has a raphe, and is shorter and narrower in woman than in man.

The *vagina* itself requires to be partially noticed. In the virgin state (and frequently after repeated acts of intercourse), it has the appearance of a passage, the opposite sides of which are in contact. The mucous membrane with which it is lined exhibits numerous *rugæ*, running transversely along the floor of the cavity, and lost on the walls. These *rugæ* are principally found in the anterior and lower portion of the vagina; and they are said to become obliterated sometimes by forcible connexion.

Signs of Virginity.—Such is a brief sketch of the natural condition of the sexual parts in the young unmarried female; and I may now add that *physical virginity* (as it is called) is usually considered as consisting in such a combination as the following:—the fresh colour, firmness and elasticity of the labia, the integrity of the fourchette, the presence of the hymen, or at least of the carunculæ myrtiformes, the narrowness and rugose condition of the vagina, and finally, a plump elastic condition of the breasts, which remain firm without support. Some add as further signs, the difficulty experienced in a first intercourse, the pain felt by the female on that occasion, together with a show of blood, in consequence of the laceration of the hymen.

Should all the preceding signs be met with in one and the same person, the fact of virginity is rendered highly probable. But the truth is, that perhaps not one in a hundred would be found *intact* in this strict sense, while the absence or modification of several of the said signs by no means rebuts the

claim of purity. For instance, there are many natural causes which would affect the state of the labia, such as disease, discharges, &c., without necessarily inferring that there had been sexual intercourse: while on the other hand those parts have been found to possess all their elasticity and apparent integrity, in young women who unquestionably had connexion. Even the hymen itself, as we have seen, may be absent without necessarily compromising the virgin character of the female. This membrane does not appear to be an essential attribute of the sex. Most virgins may have it, but many are without it. Again, instances have occurred in which virginity has certainly been infringed, without loss of the hymen. It may be very relaxed at the menstrual period, and may yield without laceration under such circumstances: and we have already mentioned that impregnation has been frequently known to have taken place without rupture of the membrane. Capuron relates an instance of his having attended a woman in labour, where the expulsion was powerfully impeded by the resistance of the hymen. He incised the membrane, which had naturally in it only a very small aperture, and shortly after, a pair of large and lively children were born. And finally, the membrane may have been lacerated otherwise than by copulation.

As to the *carunculæ myrtiformes*, they are not universally found, even where there is naturally no hymen; and they are generally considered as the relics of this membrane; so that their presence would rather be an indication of unchastity than otherwise. Narrowness, or constriction of the orifice of the vagina, is not peculiar to virgins, and it may be artificially imitated; while the contrary state, which may possibly be owing to leucorrhœal discharge, profuse menstruation, &c., does not necessarily imply that there has been a loss of virginity.

The firmness of the breasts, and muscular system generally, is but a vague sign of chastity: many widows and mothers might compare with undoubted virgins in this respect; while the opposite condition might be traced to physical and moral causes wholly unconnected with any infraction of sexual purity.

As to the other supposed signs of virginity, namely, the difficulty of a first connexion, the alleged pain experienced by the female, and the show of blood, they are of too fallacious and uncertain a description to merit the attention of the medical jurist. The first may certainly arise from relative disproportion, but may also be effected by the use of astringents, while the others may be feigned.

Ambiguity of the signs of defloration.—Thus we observe that the signs of defloration may be very ambiguous, and the more so, where little or no violence has been used, and perhaps only a single act of sexual intercourse has occurred. That there may be difficulty in pronouncing a decided opinion, even under circumstances where the reverse might be expected, is well exemplified by the following case, related by M. Parent-Duchatelet, in his valuable work *De la Prostitution dans la ville de Paris*:—"Several years ago, two young women of genteel appearance were attacked in the public streets by some young men, who called them gross and opprobrious names, and told the passers by that they were nothing better than common prostitutes. Some good-natured persons resented this conduct, and took the girls' part. A complaint was lodged on their behalf against their defamers, and the latter were summoned to appear before a magistrate. The defendants pleaded a justification, while the females, on the contrary, stoutly insisted on their purity: they even offered to submit to a personal inspection by a medical examiner,—which the opposite party dared them to do. A sworn inspector, a clever and conscientious man, was appointed by the magistrate, and the result of his investigation was this—that it was totally out of his power to say any thing certain in regard to one of the females; she might, or she might not, be a virgin; but for the other, she *probably* had had some intercourse with men, but he could not assert the fact positively. The issue of the dispute, I know not; but this is certain, that it subsequently came out that these same young women had actually been for some time entered on the registers of the police, and one proof of their being any thing but virgins, was, that they had both been, on several occasions, affected with venereal disease."

Forcible defloration.—We should not, however, be discouraged from investigation by such cases as these: we should remember that they are not instances of recent injury; and that it is generally known the sexual parts have an amazing facility in throwing off, after a time, the semblance of lesions. But the cases which we are now more immediately considering are those of *forcible* defloration, to the examination of which we are called soon after the alleged injury has been committed. The examples just alluded to may serve to warn us that we should lose no time: we should not defer our inquiry for a moment: the signs are evanescent, and if not speedily appreciated, are lost for ever. Solomon himself has compared the traces of lost virginity to the path of an eagle through

the air, a ship through the sea, or of a serpent upon a rock !

In recent cases of forcible defloration we should certainly expect to find some proofs of penetration; and these proofs would, of course, be the more convincing, the greater number of circumstances indicative of a disturbed state of the sexual parts that might appear. On the other hand, the probabilities would be the fainter the fewer the indicia. Laceration of the hymen, with marks of lesion, corresponding in their appearance with such as might have been inflicted at the time of the injury complained of, would afford a high degree of presumption of the fact; while an uninjured state of the parts would be a *prima facie* testimony against it. Where penetration alone is alleged, as having been forcible, though without rupture or laceration, we should expect to find bruises at least, or other indicia of violence about the external organs, as well as on other parts of the person. It may happen that, in consequence of a relaxed state of the sexual organs, from menstrual or other discharges, the marks of injury may not be very palpable; but even in the most relaxed condition, it would not be too much to expect evidence of injury, provided we are called in sufficiently early.

Suspicious cases. — But does it not occur to you, that light may be thrown on some cases by the complainant endeavouring to prove too much? The proofs may be redundant, or inconsistent; and when this is the case they will generally be found to be, not lacerations nor incised wounds, but, contusions superfluously produced, and without much regard to the appearances which ought to correspond with the alleged time of injury. The question may even be raised, under such circumstances, whether defloration, if it have really taken place, has been effected by the male organ? It is known that strange things have sometimes happened, when females have accidentally let slip foreign bodies, introduced for lascivious purposes, into the sexual parts. "The records of surgery," says Capuron, "supply us with many instances of surgeons being called in to extract from the vagina pessaries, glass phials, pomatum pots, and tweezer cases. And of what is not a woman capable, who is determined to be revenged on some faithless lover, or to get rid of one whom she detests?" M. Capuron then proceeds to shew how easy it would be for a female to inflict on herself such injuries as would ground a charge of violation.

A timely and judicious examination will generally expose fraudulent attempts of this kind. Foderé supplies us with an il-

lustrative case. A female child, between nine and ten years old, was said to have been violated by several persons. The mother brought the charge against them, and was rather suspected to be acting with a view to extort money from the accused. M. Foderé was commissioned to investigate the affair. He found the sexual organs of the child to be perfectly uninjured: the hymen was entire, and the little finger could hardly be inserted into the orifice of the vagina. There were, however, some marks of violence about the pubes and the external labia: a red circle, about the size of a crown piece, was observed to be impressed on the pudenda, and it had all the appearance of having been recently made. This was, indeed, the fact; for by waiting a little it gradually disappeared, having evidently been produced by the indentation of a piece of money just before the visit of the medical examiner. If the mark had been the effect of great violence, such as was stated by the mother, it would have increased in intensity, with the usual effects of inflammation. It was thus discovered to be a gross fraud, and the complainant was driven out of court with disgrace.

Evidence of emission. — To return, however, to the question already started,—how are we to know, in any given case, that penetration, or defloration, was effected by the male organ? For it does not follow that the sexual violence might not have been perpetrated by some foreign body of a different nature. Here we are driven to moral or circumstantial evidence, unless we can devise some means of procuring physical indicia; and this obliges us to consider the question of *emission* as well as of penetration.

I mentioned to you, that as our statute-law now stands, it is no longer necessary to seek for proof that emission has been effected. In the former state of our jurisprudence it was of great importance to detect semen in the vagina (as was sometimes supposed to be done), or to discover marks or spots of it about the woman's garments. Now we cannot say that it is not so still; for in almost every case where the medical man finds that there has been defloration, or violent penetration of the vagina of a female, he can go no further—he may *presume*, it is true, but he cannot *prove*, more than that something, some substance or "voluminous body" (as the French reporters call it), had been introduced forcibly into the pudenda. The case is greatly altered, however, when semen is found about the parts, for it leaves little doubt but that a *man* has been there. The discovery of semen, then, is clearly of much importance to the English medical jurist; and pains ought to

be taken in every case of alleged rape, where a personal examination is allowed soon after the injury has been received, to inspect narrowly the sexual organs, with a view to the detection of semen, and to be sure to see the very clothes worn by the complainant on the occasion.

Seminal spots.—I know not how the presence of semen has been satisfactorily ascertained hitherto in this country; but I suspect that in cases where it was said to have been detected, the medical witness formed his judgment simply from the colour, and perhaps the smell, of the stains. Such evidence, however, would not at present satisfy a court of justice; for an assertion so weighty, and fraught with such serious consequences if made good, would be, at least, expected to be corroborated by the aid of chemical science. You will do well, therefore, to note the following observations, gathered from Orfila, for they seem calculated to render your evidence on this subject in a high degree satisfactory and valuable.

When seminal fluid, or what is supposed to be such, is found on a garment—a linen chemise, for example—it forms spots of greater or less extent, round or irregular, thin, greyish, or sometimes slightly yellow, which is best discerned by placing it between the eye and the light. Pressing the spots between the finger and thumb, we find them stiff, as if they were starched: they have no smell unless we moisten them with a little water, when they immediately emit the well-known seminal odour. Holding them before the fire, taking care not to scorch the linen, the spots become of a ruddy yellow; and very often other spots, not till then perceived, are brought out by the process. And what shews that the desiccation, or drying, is alone the cause of the appearance thus produced, is, that upon moistening the stains once more they become colourless, or lose that yellowness which they had just presented. This effect of heat on the stains of semen is characteristic; it does not take place with common mucus, or with morbid discharges, such as that of gonorrhœa, fluor albus, or the lochia.

If the seminal spot be dipped in water, it is moistened all through and evenly, not as if there were any fatty matter in its composition. Whitish filaments detach themselves, flaky; and if the fluid be evaporated, it assumes the appearance and consistency of a solution of gum. When still further concentrated, it exhibits an alkaline character, as is sufficiently attested by its effects on litmus paper. “If the evaporation be carried to dryness, the residue is semitransparent, like dried mucilage, glistening, of a ruddy or slightly red-

dish hue,: and this, on being agitated for two or three minutes in cold distilled water, separates into two parts, the one glutinous, yellowish grey, sticking to the finger like glue, insoluble in water, but soluble in potash; the other perfectly soluble in water. The watery solution is yellowish, transparent, and gives a white flaky precipitate when treated with chlorine, alcohol, acetate or subacetate of lead, and corrosive sublimate. *Pure nitric acid*, concentrated, communicates to it a *slightly yellowish tinge*, though it be colourless before: *nor does the acid cause any cloudiness in the solution*—which is a characteristic test—for nitric acid added to a similar watery solution of other discharges, such as the gonorrhœal, the lochial, &c. throws down a precipitate, or whitens the fluid invariably.”

But you should know, that satisfactory as is this mode of testing the presence of semen, we can sometimes even go further. When we are called in very soon after the alleged violation, and find some fluid which we suspect to be semen in a free state—that is to say, not that which is found smeared on the linen of the complainant, but perhaps lying in the vagina—we shall probably be able to apply another test, which, if it succeed, cannot fail to be in the highest degree satisfactory;—I mean the detection of spermatic animalcules.

Spermatic animalcules.—By the application of the microscope we may be able to discover those animalcules peculiar to semen, which were first described by Leeuwenhœck, afterwards admirably examined by Spallanzani, and the existence of which Prevost and Dumas have proved in the semen of all male animals which have reached the age of puberty.

It was about the year 1770 that the Abbé Spallanzani made his valuable observations on this subject; and nothing that has since been ascertained impugns in any manner the correctness of his views. Here is the representation which he gives

FIG. 16.

of the animalcules, as seen with a powerful glass, soon after they were taken from the human body.

Their figure, while in motion, is that in the space (a), spherical, with filamentous tails: when at rest, or dead, (for while alive they seem perfectly restless) the fluid about them being dried up, they exhibit the shape seen in the space (b), somewhat oval or elongated, with a tapering tail. "The bodies," says Spallanzani, "had two distinct motions; one oscillating laterally, curving the tail from side to side; the other progressive, advancing by means of the oscillation. During this, one would suppose them blind; they strike against every obstacle; and when amidst a number, make agitations and contortions, taking at last that way where there is least resistance. They are restless and continually moving."

The representation given of them by Buffon, is this; (fig. 17.) and it is the appearance which they generally present when viewed with a microscope of no very extraordinary powers.

FIG. 17.

As to the actual size of these creatures, Leeuwenhoek says he saw 10,000 of them moving freely in a space not larger than a grain of sand. They are smaller than the globules of the blood: Raspail thinks that they are less than the $\frac{1}{100}$ th of a millimetre (about $\frac{1}{3000}$ inch Eng.), while the sanguineous globules are fully as large as the $\frac{1}{100}$ th. They are, as nearly as possible, of the same size and shape in the semen of man, of the dog, ram, and rabbit.

Spallanzani, in his loose fashion of nomenclature, called these animalcules *vermiculi*; but the scientific naturalists of the present day classify them with *Cercariae*: and "*Cercaria seminis*" is the appellation given by Mr. Owen to this human entozoon—"cui locus semen virile."

But I must not enter further into general considerations respecting spermatic animalcules, although so many temptations offer themselves in the odd theories which have prevailed respecting their use in the animal economy. There are some curious speculations on the subject

in Spallanzani; but Prevost and Dumas have broached some of the most singular. Perhaps I may add, that the opinion which seems at present to be deemed most worthy of acceptation, is, that the *Cercaria seminis* supplies the nervous system, the vascular and other substance of the foetus being pre-existent in the ovum.

These animalcules, however, cannot be observed in such a solution as that which I have just now mentioned as obtained from the spots on linen; for no doubt, by the process of drying, moistening, and transferring them from the cloth to the stage of the instrument, the creatures are destroyed, or at least so dismembered as to become unappreciable to our senses. If, however, we can obtain the semen, as I have said, in a free state, and cautiously submit it to inspection, the case will be different, even though the substance become dry. Orfila says he saw animalcules in semen which had been dry for eighteen years! But it is within the first half-hour, hour, or say two hours, after the emission, that the animalcules are most likely to be fully recognized: they are then seen in their peculiar shape—with their tails and their oscillations, performing those remarkable movements which are so characteristic of them, as to enable us to say, from simple inspection, that the liquor under examination, and in which they are found, can be no other than semen.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF LUPUS.

BY ALEXANDER URE, M.D. M.R.C.S.
Formerly House-Surgeon to the Royal Infirmary of Glasgow.

IN the following observations, which I have the honour to submit to the profession, upon the nature and treatment of lupus, it is my intention to confine the application of that term, often vaguely and indiscriminately used in nosology, to two varieties of erosive ulcer. One seated in the proper structure of the skin, the *dartre rongeante scrofuleuse* of M. Alibert; the other in an accessory part of the cutaneous organ, the *dartre rongeante idiopathique* of the same author. Proceeding in this manner, I hope farther to show, that those two, although resembling each other in many respects, yet differ in others, and consequently require certain modifications of treatment, which have not heretofore met with due attention.

Neither variety can be regarded in

the light of a malignant affection, for the reason that adjacent parts and organs are influenced, not by absorption, but simply by contact.

An affection, designated by some pathologists *lupoid tubercle*, developed at an advanced period of life, I am disposed to consider as one of a malignant type, yet bearing the impress of malignancy in an inferior degree, because implanted in a substance endowed with a low grade of vitality. It is, in fact, what I have elsewhere described as the primary cancer of the skin—the cancer of the cutaneous glandular texture, adverted to by M. Breschet, in his admirable Memoir*. On this account I decidedly protest against such misappropriation of the word *lupus*.

Lupus exedens, or eating tetter, has been defined a tubercular disease, inducing ragged ulceration of the skin. Dr. Bateman, in his Synopsis, has touched very lightly upon it, and assigns as a reason, that he can mention no remedy which has been of any essential service in the cure of it. To portray the amount and intensity of its depredations, analogous to the gnawing of some voracious animal, or the ravages of some insect, the epithets *lupus vorax*, *formica corrosiva*, were bestowed upon it by the ancient medical writers. By the Greek translators of the works of the Arabian physicians, it is described as the *ἐγρὴς ἐσθίουμενος*, corresponding to the Latin *herpes exedens*. In France, it is called *dartre rougeante*; in Germany, *die fressende Flechte*.

The common locality of *lupus* is some portion of the face. I have, however, seen it attack the nates; and M. Alibert mentions an instance of its occurring on the breast. A remarkable circumstance connected with it is, that of its being usually solitary, confined to a single point of the integument. There all its virulence seems concentrated.

I. *Erosive ulcer of the derma*.—This form is by no means infrequent. It attacks both sexes indiscriminately during childhood and adolescence; at the period of life when there exists the greatest predisposition to affections of the cutaneous and glandular systems.

The individuals most liable to suffer from this particular ulceration are those of a fair, occasionally rosy complexion,

with light auburn hair, grey or blue irides, and a tender skin. To a superficial observer, the general health seems unaffected; but on minutely investigating the state of the different functions, more or less derangement will, in the majority of cases, be detected in those of the chylopoietic viscera. The tongue is redder than natural, especially along the margins, and towards the extremity; its central portion presents a cream-coloured fur, through which the red papillæ project. The breath is more or less offensive; the evacuations from the bowels irregular and unhealthy. To these we may find superadded other signs indicative of strumous dyspepsia—an affection well described by Dr. Clark in his Treatise on Consumption.

From the survey of a considerable number of cases of this variety of erosive ulcer, I am led to coincide with those authors who look upon it as a symptomatic affection. It is generally dependent on some disordered condition in the functions connected with assimilation and nutrition. If, indeed, ever truly *localized*, it has either been preceded or accompanied, during some period of its course, by unequivocal marks of those errors of function to which allusion has just been made.

Dr. Macfarlane, in his valuable Clinical Reports, mentions that, in Glasgow, during the years 1818 and 1819, when the working classes were exceedingly ill fed, he had occasion to see a greater number of cases of *lupus* among the district poor under his charge, than at any former or subsequent period. According to M. Rayer, it has been at times extremely prevalent among the indigent in some parts of France, particularly the sterile mountainous regions of the Haute Auvergne, from scanty and unwholesome nourishment.

The affection is seated in the dermoid texture; and judging from the nature of the secretion emitted after ulceration is established, in the glandular body discerning that mucus, which, according to M. Breschet, becomes at a later period the *horny matter**. On attentively examining the process set up prior to the ulcerative absorption of the epidermic layers, the following phenomena will be remarked. In some point of the attenuated and delicate integument investing the nose, cheek, or lip, a minute yellow-

* *Nouvelles Recherches sur la Structure de la Peau*. Paris, 1835.

* *Op. cit.*

ish speck appears, surrounded by a reddish halo. The point of the skin corresponding to this tiny abscess, believed to exist in the muciparous apparatus is removed by absorption. A mode of ulceration is at length established, which is generally superficial, not extending beyond the derma; and though accompanied with preternatural redness, yet rarely with any swelling of surrounding parts. It is characterized by its ragged edges, on a level with the base; by its pale mammillary surface, whence issues that peculiar secretion which rapidly concretes on exposure to the air, into greyish yellow crusts; and lastly, by its being the seat of hot smarting pain, and occasional pruritus. The furfuraceous crusts are soon detached, and fresh ones re-produced to supply their place; the affection creeping on meanwhile with insidious certainty.

After having subsisted for some time, the original type of the disease is modified, and in some measure obscured; the surface acquires a pink glassy aspect, and loses the papillary appearance it originally presented. When situate in a part where there is much loose cellular substance, the immediately adjacent textures become indurated, condensed, and assume a dusky red or purplish hue.

Ulcers of this kind differ extremely one from another in their degree of virulence. If the nose is primarily invaded, and particularly the inferior portion of the septum, as frequently happens, the ulceration advances by imperceptible steps, corroding and consuming every tissue, muscle, and cartilage, down to the very bone, which at times participates in the devastation. The mutilation thus produced is often hideous and irreparable.

That this is not purely a local disease seems further ascertained from the obstinacy with which it resists topical agents. I have seen nearly every description of stimulant tried, and myself employed the most powerful caustics, but never have known any permanent benefit accrue, unless measures have been conjointly taken to modify the state of the system at large. I adduce the two following cases, to demonstrate the comparative inefficacy of severe escharotics, even where an extensively varied treatment had been pursued.

St. George's Hospital, May, 1836.—

Anne Paisley, aged 15, auburn hair, greyish blue irides, tolerably healthy complexion, gives the following history of her case:—

Between five and six years ago, she discovered a small hole in the lower part of the partition of the nostrils, which was constantly covered by a little dry scab. It occasioned no uneasiness. For twelve months previously, she had suffered pain in the back part of the head. At that period she was living with her parents in the country. Desirous to be rid of this crust within the nose, she consulted a physician, who prescribed tonic medicines, which were accordingly persevered in for a considerable time, without any good effect. After remaining in this comparatively indolent state for a couple of years, the affection at length extended to the exterior surface of the nose, in consequence of caustic having been applied by a surgeon in town. Since then the ulceration has slowly advanced, without intermission. The greater part of the nose, including the cartilaginous septum, is gone. The ulcerated surface, irregularly disposed, corresponds in character with the description above assigned, and is the seat of heat and smarting.

Has been for several months past a patient here of Mr. Cæsar Hawkins, who has left hardly any plan untried which science could suggest. As the disease seemed to baffle every sort of treatment, Mr. Hawkins determined to prove the effect of my preparation of the chloride of zinc*. It was accordingly applied from time to time during the

* The preparation of the chloride which I proposed and introduced into practice in this country, differs in a most important feature from that originally employed by M. Canquoin. The wheaten flour prescribed in the French formula is apt to envelop the chloride in a glutinous dough, which blunts its power, or at any rate tends to confine its action to the particles on the surface of the paste; but the anhydrous gypsum of my formula, while it can exercise no chemical action upon the chloride, forms a porous medium, through which the whole particles of the deliquescent chloride may transude upon the morbid albuminous tissue, with the effect of decomposing or destroying it with certainty to any definite depth. This preparation of mine has been adopted in several of the London hospitals, and has been found to be unfailing in its escharotic powers. It was probably owing to the counter-action of the vegetable *farina* that M. Sanson, the distinguished surgeon of the Hôtel Dieu at Paris, failed last year in the application of the paste—a fact communicated to me by M. le Doct. Nonat, in a letter dated Paris, Aug. 3d, 1835, of which the following is an extract. "Je sais que M. Sanson en a fait usage dans les cas du

months of February, March, and April, to the nasal ulceration, and likewise to two ulcerated spots which had formed near the centre of each cheek. Water dressing was applied to the eschar, and to the subsequent surface, in order to give the caustic a fair trial. Each application was attended with the most lively pain, and some inflammatory infiltration of the adjacent cellular texture. But the nature of the sore had undergone a change: it put on a sound appearance, and speedily healed. The cicatrization, however, was only partial, and in some places temporary. The disease still pursues its eroding course.

A little boy was sent to me in the spring, by Mr. Duffin, of Foley Place, for a similar affection to the above, occupying about one-half of the outer surface of nose, and extending to the cheek of same side. Beyond were traces of the *membranous cicatrix*, denoting the previous existence of the same kind of ulcer; and which I was informed had been healed by a skilful employment of strong nitric acid. There was a degree of ectropion referrible to the puckered contracted condition of the adjoining integument: the tongue presented the red dots on the grey fur. The boy had, in addition, a porriginous eruption of the scalp. In compliance with that gentleman's request I applied a thin stratum of the gypsum paste, the same as in the preceding case. Here the result was equally unsatisfactory, for the amendment was but of brief duration.

It is thus demonstrably evident, that the more powerful escharotics are inadequate to effectuate a radical cure of the affection in question, so long as the constitution is at fault; for no sooner has the effect of the escharotic subsided, than by a reflex action the sympathetic disease of the skin is again called into activity.

In the above cases the action of the remedy was to suspend for an interval that morbid equilibrium subsisting between internal and external surfaces. But no sooner had that ceased to in-

fluence, than the still existing, though latent, general cause resumed its ascendancy.

An opinion is entertained by some medical men that this species of lupus must run a certain course, or exhaust itself, ere its career can be put a stop to by any method of art. This is based, however, rather on imperfect truth than on fundamental error. When the disease is long left uncontrolled, a morbid habit is superinduced, which ordinary means fail to eradicate. But if measures be taken at an early stage to alter that peculiar condition of the system upon which the ulcerative process seems to depend, or with which it is associated, we have every reason to expect that that course will be materially abridged, and much disfigurement and mutilation prevented.

Now the chief indication is to correct the state of the digestive organs, and invigorate the system, by a proper regulation of diet, residence in a pure air, free out-door exercise; duly attending to the state of the cutaneous exhalation and alvine evacuations. Much benefit will be obtained, in most cases, by substituting for a too stimulating animal diet, one composed of farinaceous articles and milk. The patient must strictly abstain from fermented liquors, and have occasional recourse to bathing and gentle laxatives. Various alterative and tonic medicines, such as arsenic, mercury, iodine, sarsaparilla, with alkalis, steel, and sulphate of quina, will each in its turn, according to circumstances, constitute valuable auxiliaries.

When a visible melioration is perceptible in the general condition of the patient, when the different functions are all properly performed, then is the most favourable time for resorting to those topical remedies which act, not as caustics, but as powerful alteratives of the organic relations of the part. Among these arsenic claims the preference. Sir E. Home was in the practice of employing an aqueous solution of the white oxide of arsenic—arsenious acid. Dr. Macfarlane likewise advocates the use of the arsenical solution, because he has never known it produce local mischief or constitutional disturbance. His formula prescribes six grains to the ounce of distilled water. I can from experience attest its efficacy. The favourite application of Dupuytren was a powder consisting of one part of arse-

Cancer du sein, et que jusqu'ici il n'en est pas satisfait. *Adhuc sub judice lis est.*"

The new, and I believe, important fact in animal chemistry, of the action of chloride of zinc upon albumen, to which I now add that of the nitrate of zinc, first observed and stated by me; and the consequences deducible relating to the morbid albumen of cancer, are peculiarities also to which I lay claim.

nious acid in ninety-nine parts of calomel.

A topical stimulant of acknowledged utility in interrupting the progress of lupus, is the red-hot iron: it often exerts a most salutary effect in modifying the nature of the sore, producing healthy granulation and prompt cicatrization. Among other metallic stimulants the solution of nitrate of silver is found to do good in slight cases. M. Canquoin, in his work on Cancer, speaks of the chloride of antimony as a veritable specific for the *dartre rongeante*. He advises it to be used in the following way. Let the whole extent of the affected part be touched with a pencil imbued with the chloride. About a couple of minutes after, the pain thus produced is to be allayed by laying on compresses dipped in cold water. In this way the energetic chloride is at once transformed into an inert subchloride. This operation is to be repeated once every ten days, until the sore heal. Some of the German surgeons recommend the immediate application of the corrosive sublimate. The inconvenience, however, with which its absorption into the system is fraught, must restrict its use to cases of very limited extent. I already noticed the nitric acid. Before resorting to topical measures, it is always expedient to remove the crusts by means of emollient poultices. If there be much pain and heat about the sore, cold poultices ought to be employed till these subside. It is sometimes advantageous to add a narcotic solution to the cataplasm.

The stability of the cure may be inferred from the character of the cicatrix. When the new skin is soft, free from tenderness, and nearly of the natural colour, it may be considered sound; but when it remains preternaturally red and indurated, or, on the other hand, presents a delicate membranous aspect, like an *arachnoid* web traversed by minute tortuous blood-vessels, there is every likelihood of relapse. Under such circumstances it is incumbent on the patient to persevere in the therapeutic means above proposed; for it is only by repeated applications and unremitting attention that a cure can be accomplished.

This disease sometimes yields to the administration of internal remedies alone; sometimes, again, it spontaneously cicatrizes. Dr. Trüstedt, of Ber-

lin, mentions his having cured lupus by means of the decoctum Zitmanni (a compound, slightly purgative, preparation of sarsaparilla), spare diet, warm baths, and the subsequent exhibition of sarsaparilla by itself*. This practice is similar to that recommended by Rust, one of the principal surgical authorities of Germany†.

II. *Erosive ulcer of the follicles*.—This frequently originates like a catarrhal affection of the Schneiderian membrane. By and by the inflammation, being, as it were, concentrated in one particular point, leads to erosive ulceration, which almost invariably terminates in perforation of the cartilaginous septum. The only circumstances whereby the patient's attention is directed to the mischief going on, are a degree of tenderness and fulness in the membrane, felt more especially on exposure to cold air; and the constant reproduction of crusts on the point of lesion. After a time, from cold or other determining cause, some portion of the external surface of the nose becomes inflamed, and ulcerates. One or other ala, by continuity of tissue, is commonly attacked. Small red angry-looking tubercles make their appearance, and are speedily converted into a spreading ulceration. The ulcer all along preserves the tubercular character: the apices of the tubercles are more or less concealed by dry, hard, tenacious crusts‡. As the disease proceeds, fresh tubercles are developed, and encroach more and more upon the healthy integument. The confines of the sore have a dusky red hue. This ulceration is always attended by loss of substance, and the havoc committed by it when unrestrained is often very great. The parts ordinarily destroyed are the cartilaginous septum and ala. According to M. Rayer, it may begin externally, and spread to the lining membrane of the nostrils secondarily. The disease, as stated by Sir A. Cooper, consists in ulceration of the sebaceous follicles. Hence, whenever the pre-existing irritation passes along from the internal mucous cryptæ to the external ducts, the ensuing inflammation induces oc-

* Med. Zeit. f. Heilkunde in Preussen, No. 11. 1833.

† Aufsätze u. Abhandlungen. Berlin, 1834, p. 377.

‡ According to Vauquelin, who subjected them to chemical analysis, the crusts consist of albumen, some animal mucus, and salts.

clusion of the orifices, succeeded by ulcerative absorption of the follicles. The papillæ, endowed with a higher degree of sensibility, and a greater capacity for resisting the process of disorganization, may now and then be recognized forming little vascular eminences, the adjacent textures having previously disappeared. Are we to ascribe to this circumstance the extreme sensibility of the morbid surface to the impression of any stimulus?

The present variety of corroding ulcer is seldom met with before puberty. It begins most frequently between the ages of fourteen and thirty; rarely after the fortieth year, although M. Alibert has adduced cases where it occurred at a later period in life. As with the former, so also with the present form of lupus, the subjects chiefly predisposed are those of a blond complexion, with light hair and irides, and undue development of the sebaceous follicles of the nose. The latter feature may be said to characterize and accompany this sort of ulcer. Although the phenomena of strumous dyspepsia are absent here, yet the patient is seldom of a robust constitution; he feels languid; most usually labours under symptoms of indigestion; has what is commonly termed "a weak stomach." Nor does he display the clear and blooming complexion indicative of health and vigour.

As respects the intensity of its progress, we observe great variation. In one individual its course is so slow as to seem almost stationary, while, in another, it runs on with rapid strides.

In combating this form of ulcer, so obstinate and intractable in its nature, it is indispensable, towards restoring a healthy action, that we should not only destroy the morbid habit of the part, but at the same time modify the organic relations of subjacent textures. This done, the lesion will spontaneously heal. Now this twofold object can be at once accomplished by employing the chloride of zinc paste above-mentioned. In very superficial cases, a solution of the nitrate of zinc in strong nitric acid, answers the same end*. This combi-

nation resembles, in therapeutic action, the chloride, but is less energetic. I prefer it to the *nitrate acide de mercure*, recommended by MM. Recamier, Jules Cloquet, and Velpeau. One or two applications of the *paste* will at most suffice. So soon as the eschar is detached, the healthy sore is to be treated with water dressing; or if there be much unevenness of surface, with narrow strips of adhesive plaster. These ought to be symmetrically disposed, and not interfered with until they drop off. Great circumspection must be observed in using this powerful remedial agent; for injudiciously employed, it may on one hand produce a dangerous degree of erethism, on the other only irritate the sore, and exasperate the disease.

Although internal remedies are here of minor importance, still the permanence of cure will be confirmed by a judicious application of the hygienic and therapeutic precepts formerly laid down. A milk and vegetable diet, by rendering the blood less stimulating, exerts a remarkable influence upon the state of the cutaneous capillaries. This is exemplified by the fact, that nothing tends more than such a diet to subdue that capillary congestion, that turgescence of the follicles, and also to diminish that morbid oily secretion of the skin, which may accompany or follow this affection.

There is one symptom we are generally called upon to treat, as a concomitant or sequela to the ulcer—namely, a sense of tenderness or rawness of the pituitary membrane, depending on chronic inflammation. It is allayed by protecting the part against external impressions, and especially that of cold, by plugging the nostrils with charpie, or the fleecy down of finely-carded cotton wool. Where the irritation has persisted for a period of years, and is attended with superficial ulceration of the mucous membrane, some astringent lotion ought to be thrown up once or twice every day. I have prescribed, with advantage, the following liniment, used by M. Canquoin for cancerous sores:—

R. Ol. Oliv. ℥j.; Zinci Chlor. gr.xv. M. fiat linimentum.

The affected part is to be pencilled over with the liniment once a-day: in the course of a few weeks, by pursuing this plan, the membrane will be restored to a sound condition.

I subjoin the following cases, in

* Procured by dissolving one to two drachms of the fused nitrate of zinc in an ounce of aquafortis. The fused nitrate is, like the chloride of zinc, a powerful escharotic. I have produced, with a thin layer of a paste composed of it and gypsum, in the space of seven hours, an eschar about three lines thick: considerable pain and swelling accompanied its action. It is less deliquescent than the chloride.

order to illustrate the practice above detailed:—

CASE I.—E. C. Deedy, æt. 21, of a fair complexion, light hair, greyish blue irides. I saw her on the 18th February last, by the request of, and along with, Dr. Roe, under whose professional care she then was.

Right ala nasi was the seat of erosive tubercular ulceration of the follicles. There was an inflammatory blush round about the sore, which was covered with furfuraceous crusts, and the source of smarting, pricking, and occasionally shooting pain. The septum was perforated by a large aperture.

The affection commenced some years previously, inside of the cavity of the nostrils, and had progressively spread to the ala.

She had consulted many medical men, and tried a vast number of remedies, with the view of getting the sore healed, but in vain.

It having been agreed to apply the chloride of zinc, a thin layer of the gypsum paste was accordingly laid over the sore. No sooner had the eschar separated than the ulcer began to heal, and within fifteen days was completely cicatrized. For some time subsequent she took the decoction of sarsaparilla, by the advice of Dr. Roe. She now enjoys the most excellent health; the cicatrix is firm, white, and solid, and the redness of the apex has long since vanished.

CASE II.—William Blake, æt. 22, clerk, light hair, and blue irides. The sebaceous follicles strongly developed on the surface of the nose.

I was asked to see him last spring, by Mr. Pettigrew, under whose care he was, on account of an erosive tubercular ulceration of the left ala nasi, which was in part eaten away. He gave the following history of his case:—About seven years since he was attacked with a distressing tenderness of the nostrils; soon after, the partition ulcerated. The ulcerative process continued for five years; it has destroyed the greater portion of the septum. Four years ago, a crop of pimples came out upon the side of the nose, in which originated the present ulcer. There is a deep redness all round the sore. Has tried numberless remedies, internal as well as external, but without benefit. Among others, iodine and sarsaparilla; which, without meliorating the local disease, have dete-

riorated his general health. Complains of increased sensibility of the lining membrane of the nostrils, aggravated on exposure to draughts of cold air. The chloride of zinc was applied to this most refractory sore, and the result of that application has been a permanent cicatrix.

I saw this patient within the last few days. The exterior of the nose remains perfectly sound, and the morbid irritability of the pituitary membrane is subsiding under the use of a milk diet, conjoined with the topical means described while treating of this particular symptom.

CASE III.—Mrs. M***, residing at Westbourn Green, Bayswater, came to consult me for a corroding ulcer on the nose, by the recommendation of Dr. Roe. She is 32 years of age, the mother of a family: has chesnut-coloured hair, and grey irides. She informed me that the ulceration, which has the marked tubercular character, was referrible to an affection of the inside of the nose, attended with formation of scabs; that it began like a cold, upwards of two years ago: for in less than a year from that date, a little scab made its appearance on the left ala, accompanied with some inflammation. Leeches and poultices were applied, and a variety of internal remedies exhibited; and to the irritation caused by a single leech-bite she ascribes the formation of the present sore. The ulcer consists of a group of irritable-looking tubercles, covered with crusts, and accompanied with a dark-red hue of the adjacent integument. The cartilaginous septum is perforated, and a portion of the ala destroyed. Beneath the crusts she feels a constant itching, which changes to a sense of heat and smarting on their detachment. Her general health is indifferent. The sebaceous puncta are unduly prominent on the nose, which presents those minute varicose veins near the apex, termed by German pathologists *hemorrhoidal vessels*.

On the 25th June I applied a thin layer of the gypsum paste; in a few weeks after, a healthy cicatrix occupied the site of the ulcer.

She called upon me very recently. The cicatrix remains firm and unchanged. An amendment has taken place in her general health, she tells me, since the removal of the irritation maintained by the sore.

In each of the above cases the loss of substance is inconsiderable, and may be ascribed, not to the action of the remedy, but to the previous process of ulcerative absorption.

13, Charlotte-street,
Bedford-Square, Nov. 25, 1836.

INSTRUMENT
FOR
CLOSING RECTO-VAGINAL OR
VESICO-VAGINAL FISTULÆ.

To the Editor of the Medical Gazette.

SIR,

I BEG to transmit to you a description and outline of an instrument which I have invented, for the purpose of sewing together the edges of vesico-vaginal and recto-vaginal fistulæ; in the former of which cases I assisted a friend to operate with this instrument a few days ago. The long-diameter of the aperture in the bladder was situated transversely to the mesial plane, and large enough to allow the fore-finger to pass easily into it. The formation of the suture was not attended with the least difficulty, and occupied but a few minutes. I think, also, that the suture was of the best possible kind for the purpose; that is, the ligature could not cut itself out from the edges of the fistulous opening; for being passed double through opposite points of the aperture, a piece of bougie was placed within the loop of the ligature on one side, and another piece of bougie between the ends of the ligature on the other, so that the silk, when drawn tight and tied, cut only on the pieces of bougie, and the latter pressed together the edges of the aperture, forming the compound or quilled suture of the old surgeons.

The instrument, it is seen, is in the form of forceps, one blade of which is a needle, curved towards its point, close to which is its eye. The other blade is broader on its opposing surface, less curved, and at its extremity has a hole (seen in fig. 2), through which the needle point, and just the loop of the ligature, are carried, when the blades are closed. On the back of the broad blade is a spring, which, when pushed forwards, the blades being previously

closed, catches the ligature on its point, and holds it.

FIG. 2.—Back of the broad blade.

FIG. 1.

In using this instrument the operator has only to seize in its points, in the same manner as he would with a pair of forceps, the border of the fistulous opening: the blades should then be closed, and the ligature will be carried through one lip of the aperture. The opposite border is then to be seized, and the blades to be closed and held so. The spring on the back of the broad blade is now to be pushed forwards, by which the ligature is caught and held at its point. The blades are then to be opened and gently withdrawn, leaving a double ligature passed through opposite points of the fistulous aperture, so that a common or quilled suture may afterwards be formed.

I have the honour to be, sir,

Your obedient servant,

WM. BEAUMONT.

	<hr/>
Total number dismissed during the year	50
Total number remaining in the Asy- lum, 1st May, 1836	107

From the foregoing table, it will be seen that thirty-seven patients have been admitted during the year; twenty-six of whom were considered, at the time of admission, to be curable, and the remainder incurable. The admission of so large a proportion of incurable patients is always much to be regretted, seeing they tend to injure the character of the Asylum, as an institution for the cure of insanity; and for this, as well as for other reasons, it does appear to be inadvisable for the managers to sanction the admission of so many patients of this description, *unless where they are distinctly proved to be furious, and dangerous to the public, and altogether unmanageable at home.* I am happy to observe, however, that the gentlemen of the visiting Committee, for the last two quarters, have shewn a desire to act on this principle; having refused to sanc-

tion the admission of idiots and other *harmless incurables*, who, it is very evident, cannot be benefited either in their mental or corporeal condition, by being shut up for life within the walls of an asylum, in a state of idleness, occupying the room that might be appropriated to others, with an infinitely greater prospect of benefit, as well to individuals as to the public at large, and to the character and general prosperity of the institution.

The table also exhibits the number of those who, in the course of the by-gone year, were considered to be fit subjects for the medical and moral treatment of the institution, and who, accordingly, have been duly subjected thereto. The total number of this class of patients was forty-nine. Twenty of them have been already discharged fully recovered: whilst four more have been sent home in a greatly improved condition, along with five others less improved.

It thus appears that twenty-nine, out of the forty-nine curable patients, have been more or less benefited by their residence in the Asylum, and already discharged; and that the number of cures is in the proportion of rather more than two-fifths of the number of those who have been placed under treatment, which is considerably above the average proportion of recoveries in most of the large public hospitals for the insane, as laid down in the statistical table, drawn up by Esquirol and others. And I may here also be permitted to observe, that a like proportion of recoveries has been obtained on an average of the last six years; for out of 279 patients who have been subjected to the curative treatment of this institution, within the period just mentioned, 115 have been recovered, exclusive of thirty-three who have been dismissed, partially recovered.

Of the four principal modifications, or species of insanity — viz. mania, monomania, dementia, or acquired fatuity, and congenital fatuity, or idiotism—the two first only are considered to be fit subjects for medical treatment; the two latter being generally believed to be hopeless, or nearly so. No less, however, than ten of these incurable individuals have been admitted during the year, and, in some of these instances, palsy or epilepsy was combined with the insanity. The cases of mania wherein there is general disturbance of

the intellectual functions, with violent excitement, are unquestionably by far the most favourable for cure; and it is surprising how soon a change for the better takes place in the condition of such persons, when removed from their friends and put under an early and judicious course of treatment. In several instances of this kind, a most striking improvement has been observed within a week or two after admission; and this has even occasionally happened when, for some weeks previously, the complaint had been pursuing its course with much violence, and without intermission: although it must be confessed, that in other instances, where the treatment has been so long deferred, hopeless fatuity has been the consequence. These are facts which, I think, cannot be too often or too strongly urged on the attention of the friends of insane patients, in order that they may learn, by a well-timed removal from home, to secure for them, as far as possible, the chances of a recovery; and thus to save them from the risk of that complete and permanent overthrow of the mental powers, which is so apt to ensue whenever the violent mental and bodily excitement, so characteristic of mania, is left to pursue its course uncontrolled.

The remedial means which have been adopted throughout the year, in the treatment of the different cases, have of course been varied, according to the nature and urgency of the predominating symptoms—insanity being a varied and complex disease, both as regards its causes and its phenomena. In regard to what is usually styled the moral treatment, I may just observe, that, in accordance with the established fact—that occupations of a kind fitted to engage the *attention* and encourage *exercise* in the open air, are highly conducive to the cure of insanity—every possible opportunity has been seized of giving effect to this important principle, so soon as the patient was brought into a state capable of being benefitted by it. I still, however, regret to say that the field of occupation is altogether inadequate to the exigencies of the establishment, so far, at least, as relates to the male side of the house; and consequently, that in this very essential particular, the institution is defective. I trust, therefore, that the managers

will again take this matter into their earliest consideration; and I feel pretty confident, that when we are furnished with more suitable and constant employment than we at present possess, not only a greater number of patients will be recovered, but several others not susceptible of a *complete* recovery will be gradually trained to habits of regularity, and at length brought into such a condition as to render them in some degree useful members of society, and safe to be at large. It is hardly requisite to adduce any arguments in addition to those formerly embodied in a special report, which I presented to the managers in reference to this subject in 1834; it will be sufficient, I think, to quote the opinion of the celebrated Pinel. The following are the words which he employs, in speaking of an establishment in Holland, where the number of recoveries was very great, compared with other establishments in which employment formed no part of the curative treatment. “The patients are divided early in the morning into parties, some of whom are required to assist in various household offices, while others are conducted to the work rooms, furnished with the implements of their respective trades. But the majority are distributed, under the superintendence of the keepers, through a large inclosure, where they are occupied in gardening and agriculture. Uniform experience has proved the efficacy of these labours; and it is particularly to be observed that those of the higher ranks of life who live in the same Asylum, but in a state of idleness and sloth, retain their lunacy and privileges together, while their inferiors are restored to themselves and to society.”

With reference to the causes which gave rise to insanity, in the different individuals who have been admitted during the year, we find that twelve of them were traced to hereditary predisposition; two to congenital imbecility; five to a highly scrofulous constitution of body; five to domestic afflictions—pecuniary embarrassments—grief, and other depressing passions; six to inebriety, and other demoralizing habits; two to an hysterical constitution, and previous attacks; two to an interruption of the uterine functions; one to injury of the head from a blow; one to child-

birth; one to epilepsy; and one to a severe febrile attack; whilst two arose from occult causes; in other words from causes which could not be traced, or had nearly escaped detection.

Notwithstanding, however, that such appear to have been the more prominent of the remote causes, there was unquestionably in a good many instances a combination of these in operation, all tending to the same end, some of them of a predisposing, and others of a more immediate or exciting nature. The causes of insanity are, indeed, often obscure; but in general it will be found that several have been acting simultaneously towards its production, and also, that, in a majority of instances, there is an hereditary predisposition to it.

I have only further to observe on this head, that four of the female patients, who have within these last six years been discharged convalescent, have been re-admitted after the lapse of some months, or it may be one or more years, labouring under fresh attacks; but that these secondary attacks have been comparatively rare amongst the males. Females would seem, from their peculiar habits of life and situation in society, to be at all times more under the influences of the moral than the physical causes of disease. And as it is very difficult, if not in most instances impossible, to withdraw an individual entirely from the operation of those of the former class, we are, I imagine, from this circumstance, enabled to account, in some measure at least, for the fact that they are more subject to relapses or recurrences of their complaint than males.

Eleven patients have died during the year. Seven of these were aged and confirmed lunatics.

A post-mortem examination was instituted in every one of those fatal cases (with consent of the friends), and the appearances carefully noted. Lesions of the brain or its membranes, and sometimes of both together, were found in all of them; and although the morbid appearances in this region of the body were not in every instance precisely similar, yet were they substantially alike. Other organs of the body were also occasionally found in a state of disease. Thus five of the male patients died with symptoms of palsy and fatuity, and in all of them were discovered unequivocal

traces of disease of the investing membranes of the brain, along with copious depositions of a serous fluid beneath the same, and into the ventricles. Another male patient who had long been subject to epilepsy, and who died of ileus, exhibited disease of the brain, as well as of the intestines. The last of the male patients who died, and who was in a state of fatuity when admitted, also exhibited traces of cerebral disease. The first female who died had been long subject to insanity: she exhibited marked disease of the cerebral membranes. The second was a young girl, who laboured under congenital idiotism, and whose mother has been long an inmate of the institution: she died of pulmonary consumption, and exhibited a tubercular formation in the right hemisphere of the brain, besides extensive tubercular disorganization of the lungs, peritoneum, spleen, and other abdominal viscera. The third person who died among the females had been for some time subject to violent paroxysms of mania: she also exhibited traces of cerebral disease, and two tumors were found in the cavity of the abdomen, besides intense injection of the inner coat of the stomach and bowels; the one tumor was attached to the stomach, and the other to the liver, and the irritation which they had excited in the organs with which they were in contact, appeared to have operated as the immediate cause of the maniacal paroxysms. The last was a young woman, who had been long subject to epilepsy, and was fatuous at the time of admission, and who died from exhaustion, consequent on the violent struggles which she had long sustained: the brain and its membranes were in this case much injected.

In reference to this brief statement of the morbid appearances in the fatal cases, it is worthy of remark, that while five of the deaths amongst the males were preceded by a state of palsy, not one of the women exhibited this condition; and, moreover, that the morbid appearances were precisely similar in all those five cases. This circumstance I have also noticed in the fatal cases of former years. I can recollect, indeed, of only one instance of a female patient having exhibited symptoms of palsy during the last six years, whereas not less than a third of all the male patients

who have died within the same period, had, previously to this event, fallen into the state referred to. It appears to me, that we ought to look to the differences in the nature and mode of operation of the exciting and predisposing causes, to which the two sexes respectively are most apt to be exposed, in order to obtain an explanation of this remarkable difference in the *termination* of insanity, in male and female lunatics. The males, for example, are more exposed to powerful causes of a *physical* kind, especially the abuse of spirituous liquors, tending greatly to the production of *inflammation* of the brain, and its consequences; palsy being, together with derangement of the mental faculties, one of these consequences: while, on the other hand, the females are exposed to those *moral* causes which rather beget a state of *nervous irritation* than of inflammation.

Such of the patients as are in a quiet and composed state of mind, and are not impressed with delusions likely to be aggravated by religious exercises, are permitted to join regularly in public worship. The attendance of the patients on devotional duties, when conducted in public, and under the limitation to which I have just referred, has, I think, been equally productive of the good effects (particularly in calming the passions) that are reported to have accrued from it in other establishments of a like kind.

In conclusion, I have to observe, that amongst other arrangements for securing the welfare of the inmates, and a due regard to their feelings, and the feelings of their relations, it has been the practice for a considerable time past to deny strangers access to those departments of the house that are occupied by the patients during their waking hours, unless under particular circumstances; such, for instance, as in the case of a medical visitor, or one really in quest of useful information. The Aberdeen Asylum has, therefore, been rendered in this point of view as much a private establishment as any other which goes under that name; and as much so as is consistent with a just measure of public surveillance, always highly proper as tending to keep up its respectability, and to correct any abuses which might otherwise be apt to creep into such institutions. Thus no one can gratify idle curiosity at the expense of wound-

ing the patients' feelings, whilst every thing that is fitted to meet the eye of casual visitors is still open for inspection.

JOHN MACROBIN, M.D.

Aberdeen, Nov. 11, 1836.

[We are happy to be able to add, that Dr. Macrobin has received the thanks of the Managers for the manner in which he has discharged his duties, and that the suggestions made by him in the above report have been acted upon.—ED. GAZ.]

BROMIDE AND IODIDE OF IRON.

To the Editor of the Medical Gazette.

SIR,

IN consequence of a paper which appeared in the last GAZETTE, respecting bromide of iron, by Dr. Kemp, of Cheshunt, I am induced to trouble you with a few remarks. It is more than two years since I first prepared it for the medical profession in town, during which time several have prescribed it; and from my own experience I venture to assert, that it has no advantage over the iodide of iron, as to its keeping when dissolved; one undergoes decomposition quite as soon as the other; but both are easily kept in a perfectly neutral state, by inserting a bunch of iron wire, or a coil of the same, long enough to traverse the whole column of the solution.—I am, sir,

Your most obedient servant,
P. SQUIRE.

277, Oxford-Street,
Nov. 28, 1836.

ANALYSES AND NOTICES OF BOOKS.

“L'Auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D'ALEMBERT.

The British Medical Almanack, 1837.
Edited by W. FARR. Sherwood.

British Annual and Epitome of the Progress of Science, for 1837.
Edited by DR. R. D. THOMSON.
Baillière.

The Medical Almanack, for 1837.

Published by the Company of Stationers.

The Medical Pocket-Book, for 1837.

By JOHN FOOTE, M.R.C.S.

THE first on the list is decidedly the *business* almanack for the profession: it is superior to any thing of the kind that has yet been produced; there are, however, several points in it which shew that the editor has not profited as much as he might have done by his three years' experience. We have met with some mistakes, and not a few omissions: nor are these of a trifling nature. It is both a great mistake and an omission, to set down all belonging to the College of Physicians in alphabetical order, putting the Fellows, Licentiates, and even the Candidates, in one common list; and the late statutes, so important to the medical public, are wholly unnoticed, as if they had no existence. The recent ordinance of the College of Surgeons respecting teachers of anatomy is omitted, although published in this journal nearly a month ago. "Wakley's Act" is left out—*query*, does the editor intend by this to express his opinion of its true value? The title of Doctor is unceremoniously taken from the hospital physicians and teachers, in London, by way of economising space(?); while it is partially given to those in the provinces. The school of anatomy belonging to St. George's Hospital is stated to be in Grosvenor Place, instead of Kinnerton-street. Mr. Bage is mentioned as assistant-apothecary to that hospital, instead of M. Depasquier. Creosote is talked of precisely as it was in last almanack (much of the pharmacopœial part being merely reprinted), as if nothing had been ascertained since regarding the real value of the medicine; and no antidote is given for arsenic except "hydrated tritox. iron in thirty times the quantity of the poison."

We are sorry, too, that we cannot give unqualified praise to the author of the paper on National Statistics; for he adopts a tone of censure and dogmatism throughout which we think is neither warranted nor becoming. A De Moivre or a Laplace could not, and we are sure would not, assume so magisterial an air. Perhaps the more modesty a writer evinces in laying down principles in statistical science

the better: statistics are only in their infancy; and it is worthy of the phrenologists alone to plunge confidently beyond their depth into a sea of assumptions, where there is nothing certainly known beyond the first few footsteps.

The price of the almanack, we must add, is very unreasonably increased: last year we had 160 pages for 2s.; this year only 216 for 3s.; while the supplemental matter contains so much that is really objectionable—unsuited, we should say, to the pages of an almanack.

The editor of the BRITISH ANNUAL has aimed at the production of a yearly periodical suited to a much larger class of the community than that composed merely of the members of the medical profession. To the latter, as well as to scientific readers generally, he here offers a year-book on the plan of the well-known French *Annuaire*, only modelled so as to be more particularly useful to the British public. Besides containing all that is really valuable in the French production—*minus* M. Arago's essay, whatever it is to be for next year—the Annual before us is enriched with some excellent scientific articles. The editor himself supplies a paper on the Progress of Vegetable Chemistry, and the Rev. Baden Powell a comprehensive and able report on the recent progress of Optical Science. Mr. Woolhouse gives a sketch of the progress of Astronomy, and Mr. Davies a curious and learned history of Magnetic discovery. The whole forms a handsome little volume, with which we are very much pleased, and hope that the experiment may be as successful as it is commendable.

The Almanack of the Stationers' Company is a very poor affair. No pains seem to have been taken to procure correct lists of any establishments save those of the Metropolis: the returns, for example, of the Irish and Scotch Colleges are not sufficiently recent, and even the Metropolitan announcements seem scarcely to be relied on. If the Company cannot find some active intelligent medical man to edit their production in future, they had better not trouble themselves with providing an almanack for the profession.

Mr. Foote's "Medical Pocket-Book" contains much less than any of the others—yet has some of the things in

which the most bulky of the others is deficient; such as the new statutes of the Corporate Bodies, and the Medical Witnesses' Act. There is, however, in every way a littleness about it—half the bulk is blank paper, too scanty for memoranda or for any other useful purpose.

MEDICAL GAZETTE.

Saturday, December 3, 1836.

"Licet omnibus, licet etiam mihi, digultatem
Artis Medicæ tueri; potestas modo veniendi in
publicum sit, dicendi periculum non recuso."

CICERO.

OPERATION OF "WAKLEY'S ACT."

WHEN the Medical Witnesses' Bill had received the sanction of Parliament, and thus became a law, we ceased to dwell on the distrust which we had previously expressed of it; and, uninfluenced by any of those personal feelings which the parent of this defective act, judging of others by himself, has never failed to attribute to us, we gave to the measure our hearty and active support. Several editorial notices regarding it are to be found in our pages, and one entire article was devoted to its exposition. In reviewing our efforts in its favour, the only circumstance with which we can reproach ourselves is, that we were over-liberal, and in our anxiety to prop what was evidently so weak as to require assistance, suffered ourselves to be led into expressions more favourable than the result has proved it to deserve.

The Medical Witnesses' Act—notwithstanding that it was drawn up, we are informed, by his friend Mr. Theobald, the special pleader, and lecturer on Medical Jurisprudence—has proved a failure.—The labour and responsibility to which it exposes all our professional brethren, but especially the general practitioner, are most inadequately remunerated by its provisions; and the

recompense which the law allows is clogged by so many impediments to its acquisition, as to have in many instances rendered it altogether unattainable. To the fact of the fee being, under particular circumstances, wholly disproportionate to the sacrifice of time and talent, we have already in a former article alluded; but as this is a point which does not at first sight seem very apparent, we shall now more particularly illustrate it.

If the medical man were merely called upon to attend the Coroner's Court, and having given his evidence, at once to receive his fee and retire, the sum awarded to him would doubtless be sufficient; this, however, is very far from being the case, as the subsequent details will shew. But besides the trouble and loss of time which, according to the present system, attends the attempt to obtain remuneration, there is this great defect in the act—that however often an inquest may be adjourned, and however often the witness may be compelled to be present, his collective attendances are nevertheless reckoned but as one, and entitle him but to a solitary fee. Now one effect of the bill has been to induce coroners to dispense with medical witnesses as much as possible, so that they are chiefly had recourse to in cases of obscurity, and in such, one sitting is often insufficient to lead to a decision. The witness, however, has to be in attendance; and instances have occurred in which the Coroner has sat four or five times upon the same body; while we have the *ex cathedra* assurance of the member for Finsbury himself, that however often the witness may have attended under such circumstances, he is entitled to no more than one guinea. It is quite obvious that the estimate here formed of the value of a medical man's time is preposterously low, and that one tithe of the real interest for the profession to which the father of this

act lays claim, would have induced him to make the fee a guinea at least for every separate day on which the witness was compelled to be present.

But again; if a post-mortem examination be required, another guinea is awarded—no more, certainly, than the service merits. Well; having earned his additional guinea by a laborious autopsy, it may be that the evidence is not yet sufficient, or the worthy Coroner or the jury may be fond of scientific pursuits, and choose to have the contents of the stomach analysed. The witness is instructed to enter upon the required manipulations. Here begins by far the most difficult, the most tedious, and the most delicate portion of his task—one requiring apparatus, reagents, skill, and time. All these, however, we shall suppose have been at his command, and he appears once more before the Coroner, to communicate the result of his researches. What remuneration, most courteous reader, should you deem sufficient for all this time and scientific labour? At what do you conceive the framer of the Act estimates this part of the services of the general practitioner, on whom he professes to have bestowed so great an obligation?—why simply and absolutely at *nothing*. It may appear incredible, but such is the plain unperverted truth. Not one *sous* is awarded for the analysis. The contents of the stomach cannot be examined without opening the body; if the body be opened, the party is entitled to a guinea for having done it; and if he be "ordered" to institute the laborious chemical process alluded to, he gets not one farthing more. True it is, that the *honourable* framer of the act is pleased to say, that if the witness analysed the contents of the stomach, the Coroner would be "justified" in giving an order for another guinea. Oh, most provident legislator!—most

wise and upright expounder of the law!—already do Coroners hesitate in giving one guinea for such examination, notwithstanding that the law allows it; yet would they be "justified" in giving an order for more, although such proceeding would be in direct violation of this learned commentator's own "act." Overseers, already indisposed to pay, would delight in this as an infringement of the statute—which would assuredly "justify" them in refusing the whole. A rare expounder of his own wise act, say we again—yea, a second Daniel!

But however monstrous and absurd the above declaration of our contemporary may be in other respects, it is at least of value in this—it is an admission that his Bill has provided for the witness less than his services fairly merit;—a defect which we pointed out some months ago.

We have hitherto assumed that what the act professes to bestow, the party entitled to it can readily obtain, but we regret to say that the statements which have appeared in the daily papers, and the repeated applications which have been made to us on the subject, clearly prove that obstacles of the most vexatious kind present themselves: medical men are called upon as witnesses, and then on seeking for their fee, frequently do so in vain: some instances there may possibly be in which the fee has been obtained,—but there are already numerous examples in which it has been refused altogether.

It is quite clear that, as the law stands, the medical witness is entitled to a fee; and seeking an explanation of the difficulty he experiences, we find two circumstances which mainly lead to this result; the first is, the disreputable parentage of the Act, which has taken from it all the moral influence which is calculated to assist the operation of a new law. Parish authorities have in

their wisdom conceived a notion that, as it is only "Wakley's Act," they are "justified" in resisting it. This is the doctrine maintained in a public letter addressed some time ago to the *honourable* member for Finsbury, by "an Overseer of St. Pancras,"—of which letter, by the way, that worthy has had the prudence to take no notice*.

But another and more important impediment to the operation of the act is, the facilities which its defective construction affords to evade the demand. In order to become entitled to his fee, the witness has numerous steps to go through; and first, he must be certain that he has got a proper "order" to attend. His actually attending,—the requiring and obtaining of his evidence by the coroner's court,—avail nothing, if the slightest imperfection or irregularity exist in making out his summons; and in this manner, from accident or design, many have already been cheated of their money. Secondly, having attended, he must procure another "order" from the coroner for the sum to which he is entitled. It might, indeed, be supposed that no risk could be incurred here, if the preliminary step had been attended to; but not so,—the coroner may demur; and in various instances has done so. True there is redress—most satisfactory redress; for we are told by the *honourable* authority above alluded to, that the party aggrieved has only to bring an action in the Court of King's Bench against the recusant coroner. Oh, most happy device!—most profitable pastime!—bring an action to recover an "order" for the sum of one pound sterling; which order, when procured, *if procured*, may or may not be honoured! And

this brings us to the third stage of this eventful history—that, namely, at which the witness, having seen to the correctness of his first order—and having attended—and having given his evidence—and having made a formal application to the coroner for an order for his fee, more lucky than many, has obtained it. Thus armed, he now proceeds to the overseer; but this functionary probably cannot venture, upon his own responsibility, to make so great an outlay, and desires him to call again: perhaps he requires a consultation with his colleague in office, or with the other parish authorities; and after laying their wise heads together, they resolve to refuse the fee, and let the "Doctor" do his worst. This is bad enough; but still, as we are assured, there is redress: he may go to law a second time—aided, too, by all the experience which his former suit has afforded him.

These are no imaginary evils—no merely supposititious cases—the several obstacles to payment above enumerated having actually occurred, and having been brought within our cognizance by the complaints of correspondents. There are numerous instances in which medical men have been fain to go without their fee, after having been put to a great deal of trouble. But however harassing and vexatious this may be, no one has hitherto been provoked into the imprudence of going to law for so small a sum.

Now these considerations have certainly altered our opinion of the practical benefits to our profession likely to result from "The Medical Witnesses' Act;" and we have freely given expression to those misgivings. But we were not prepared for the indirect admission of its failure which our remarks (in the *GAZETTE* of this day fortnight) have drawn from the profound and upright legislator, with whom it originated. Conscious of what has occurred

* A Letter from an Overseer of Saint Pancras, to T. Wakley, Esq. M.P., Editor of the *Lancet*, repelling the unjustifiable Attack made upon the Overseers of Saint Pancras, for exposing his inefficient attempt "To provide for the attendance and remuneration of Medical Witnesses at Coroners' Inquests." London, 1836.

to many of those who have attempted to recover under his act, and anticipating what is to follow, he puts forth the cool and deliberate falsehood that we have instigated overseers not to pay the fee; and follows this up with another assertion, equally mendacious—namely, the fifty-times repeated tale that it is our hatred of general practitioners which has made us do so. The latter assertion is an old trick of Wakley's, which does not require exposure; as to the former, we have merely to refer, in proof of its falsehood, to the articles upon the subject which have appeared in our pages. But further: the *honourable* member knows well, that even if disposed to injure his Bill in the estimation of overseers, such proceeding on our part would have been entirely one of superelevation; the letter above alluded to, from an overseer of St. Pancras, in which he is set at defiance, and his Act held up to "ridicule and derision," having been printed and circulated nearly *three months ago*!

That Mr. Wakley had chiefly in view his own glorification when he penned the Act, his sickening and merciless iteration of "our parliamentary labours" clearly proves; but that he also intended to confer a boon upon general practitioners, who must be principally called upon as witnesses, we nothing doubt. It was on the latter account that we encouraged the measure, and exerted ourselves in its favour. The importance attached to our co-operation by the *honourable* member for Finsbury, is proved by this—that *he sent us the Act in slips from the Lancet Office before it was published, so as to secure its appearance in the MEDICAL GAZETTE a week earlier than could otherwise have been the case* (viz. August 20, 1836). Again: uninfluenced as we ever have been by personal hostility, and preferring to forget for a moment the habitual prosti-

tution of his pages to the vilest purposes, we farther besought the favourable opinion of the profession towards him, as one who, in this instance at least, had done his best to lay them under obligation. And so highly was this poor compliment of ours appreciated by our contemporary, that it was straightway transferred to his pages through the medium of an anonymous letter—*evidently written by himself*.

We cannot close this article without alluding, in terms of indignation, to the scandal of seeing an adventurer, to whom accidental circumstances, at a moment of political excitement, gave a seat in the legislature, endeavouring to convert this event, by indirect means, to the purposes of private gain. Not content with childish and eternal references to his own parliamentary career—heedless of its notorious failure and insignificance—he attempts to procure purchasers for his journal by holding out his own "act," *in terrorem*, over the medical profession. He publishes lectures on Medical Jurisprudence, and then appends as a standing notification, that the enactments of the Medical Witnesses' Bill render it impossible for practitioners to neglect the subject, "*without exposing themselves to the risk of irretrievable ruin and professional degradation*."

Thus, then, it stands:—if the practitioner does not obey the summons of the coroner, he has the certainty of being fined 5*l.*; if he does obey it, he has a chance of getting an order for a guinea, which he is at liberty to recover—if he can; but if he has not purchased *Lancets* enough to enable him to make a good figure in the court, then is he exposed to "irretrievable ruin." Such are the obligations conferred on the medical profession by the legislation of Thomas Wakley, M.P. for the district of Finsbury!!

CLINICAL LECTURE,

Delivered at St. George's Hospital, November 25, 1836,

By DR. SEYMOUR.

FEVER.

I SPOKE at our last meeting of those cases of fever which had been taken in a few days before, and which were under my care. All these cases are convalescent.

SCARLATINA.

There was one case of fever, however, which differed from the others, and of which I will endeavour to speak to-day—more especially, because it is a disease at present very rife in London, and the treatment of which is of very great importance. I allude to *scarlatina*, or *scarlet fever*, as it is called.

A case of this disease was taken in on Wednesday week, and is in York ward. It occurred in a youth named CHARLES TURNER, set. about 20. It is a very moderate case of the complaint, so far as the urgent symptoms are concerned; at the same time, it is better to take one of these ordinary cases, and explain the accidental circumstances which arise during its progress, than to take a very severe case, such as you may not see again for a great length of time. This man's case is called *scarlatina anginosa*. Nosologists have divided *scarlatina* into *S. simplex*, *S. anginosa*, and *S. maligna*. The latter is the same disease as the ulcerated sore throat of Huxham and Plenciz, and one of the most fatal diseases with which I am acquainted. This, however, is an unusual form of the disease; whereas, the other species is very common. The circumstances which accompany the disease make it of great importance, in a practical point of view, to attend to the eruption with which it ordinarily begins.

I should tell you that people have got an odd notion into their heads; they imagine that *scarlatina* means something else than scarlet fever. This, it is said, is to be attributed to the late Sir Walter Farquhar, who, to calm the fears of people, when it prevailed to a great extent, said that it was only *scarlatina*, and by using this diminutive, they thought it was another disease, whereas *scarlatina* is only the Latin name for all the varieties of the complaint.

The eruption almost always comes out on the second day of the disease, but sometimes not until the third. In the present case, two full days elapsed before the eruption appeared. This contradistinguishes it from measles, in which the eruption never comes out before the fourth

day—a difference of time which enables us to form a correct diagnosis. The diagnosis between measles and scarlet fever, although sufficiently plain in general, is sometimes very obscure. The eruption is generally efflorescent, and not raised in the semi-circular form in which it occurs in measles, in addition to which it is almost always attended with a sore throat. In the early stages of the complaint, the danger of the patient is exactly in proportion to the degree of severity of the sore throat. In general the tonsils are swollen, and of a bright scarlet colour. About the second day there begin to appear slight eminences, which sometimes coalesce, forming sloughs. If they coalesce early, and the sloughs are ash-coloured, the disease is extremely dangerous; the impression made on the nervous system is so great, that the patient dies on the 2d, 3d, or 4th day of the eruption. Indeed, it was the death of patients under this complaint having been of a more than usually appalling character, which gave rise to the great efforts made by the profession generally to treat it. It was not, however, known to the ancient physicians, but described by Huxham, and great attention called to the severe epidemic which occurred in 1747. In that epidemic, two sons of the Right Honourable—Pelham, then Chancellor of the Exchequer, died within an hour on the same day. Of course such an event, particularly in the higher classes of society, was a subject of great excitement. I suppose that similar accidents happened frequently in the course of that epidemic. In consequence of this, physicians began to investigate the subject, and Dr. Fothergill produced a work on Ulcerated Sore Throat. In the case which we are considering, the throat early became violently affected. There appears to be a sympathetic effect on the nervous system, and patients are destroyed very rapidly. A boy, to my knowledge, may be perfectly well on Thursday, and dead on the following Saturday morning.

This patient was attacked on Sunday night with vomiting, rigors, and pain in the back—commonly preceding symptoms; and on the Wednesday morning, leaving Monday and Tuesday clear, he first observed red efflorescences on the skin; probably they came out a little earlier, but were not perceived. He had a blister applied to the exterior of the fauces, which I beg you to observe is, for reasons I will presently explain, very bad practice. The blister, however, relieved the swelling, and in this instance did no harm. The whole of the membrane of the mouth and throat became of a scarlet-red colour, and there

was some pain on inspiration referred to the scrobiculis cordis. The skin, when I saw him, was moist, an unusual circumstance; the pulse was 110, and not weak; and the bowels had been opened by medicine.

I mentioned that the application of a blister is always bad practice, and for this reason, that there is a great degree of irritation about the mouth and throat, and sometimes a blister acts as a direct stimulant, unless other remedies be used, and constant fomentation. In hospital practice this is doubly unjustifiable, because erysipelas is apt to come on. There was a nurse in the hospital not long ago, in whom this accident occurred, and she was in a very dangerous state. After the scarlet fever was over, she nearly died from the irritation of a blister inducing erysipelas. Where you think counter-irritation useful, a mustard poultice applied just long enough to excite redness, will be sufficient, and is often very beneficial. But in general, where the fauces are much inflamed and swollen, the application of leeches to the throat is the most effectual practice. In fact, your attention is directed, in the early stage of the complaint, to diminish the heat of the skin, which is excessive, and to reduce the swelling and inflammation of the fauces. If the heat of the skin be steadily above the natural temperature—and I should observe that in this disease it is more commonly above the natural standard than in any other febrile affection known in this country, being frequently 104° Fah.; and if the eruption be full and red—the best thing that can be done is to put the patient into a shower bath, or into a tub of cold water—cold affusion. But in private life people will not submit to this; they are greatly alarmed by it, and therefore the next best thing is to wash the body over with vinegar and water. This may be done several times a day, and the effect is, to diminish the heat of the skin. The next point is to get the bowels freely opened, and to diminish the inflammation. It is seldom that blood-letting is necessary; but if the symptoms are very violent in the early part of the case—if the skin be hot, and the eruption has already come out—there can be no objection to taking blood from the arm, though it is not often necessary.

With regard to getting the bowels open, swallowing is always a matter of great difficulty, but the object may be effected by putting a couple of grains of calomel on the tongue every four or six hours, and exhibiting, as soon as possible, two drachms of sulph. magnesia in an infusion of roses. In most cases this is sufficient.

I should say something respecting gargles. In the first place, it is seldom that a patient can gargle the throat at all, and then the simple inhalation of the steam of hot water is the only thing to which you can have recourse. If the patient can swallow warm bread and milk, it acts as a fomentation: the best gargle you can employ is hot barley-water. Do not begin in scarlatina with an astringent gargle, for I have seen very serious effects arise from it; the throat has become more inflamed, the patient a great deal more distressed, and the practitioner, I remember, in one instance was turned out. Commence with applying warmth as much as you can to the throat, which relieves the swelling of the tonsils, and in the course of time the disease will go away. You must keep the bowels open by a saline powder, and place on the patient's tongue, at first every night, and in a short time every other night, two grains of calomel with sugar. This, with simple gargles, is almost all that is required in ordinary cases.

But the disease sometimes does not stop here; and you must bear in mind, that the most dangerous sequelæ in scarlatina occur after a mild rather than a severe eruption. These sequelæ are of various kinds. Sometimes inflammation of a serous membrane takes place, more especially of the pleura and pericardium. I have seen a patient come into the hospital with the secondary affection, and I have seen two quarts of matter taken from the pleura after death, in consequence of inflammatory action having been set up there subsequently to the decline of the original disease. I have known two cases in private life, where children died from inflammation of the pericardium, after they appeared to be safe. Inflammatory symptoms will sometimes take place in the serous membrane of the bowels; but this is not very common.

Another case which occurs after the subsidence of scarlatina is the swelling of the parotid and submaxillary glands. This frequently occurs, likewise, towards the end of continued fever, and has been looked upon as critical, as ending the complaint. If the parts slough, which they rarely do, it ends the case very decidedly; but if this symptom disappears, it is generally considered as not disadvantageous. I do not know whether this can be said to be the case in scarlatina.

The patient whose case is before us was admitted on the 9th, and I ordered two grains of calomel, and two grains of sugar, to be placed on the tongue every six hours, and two drachms of sulphate of magnesia to be given in an infusion of roses twice a day. On the 11th the eruption declined

rapidly, and the pulse was only 80. On the 14th the disease entirely disappeared. Nothing could be more easy than this. But though the scarlatina had disappeared, the case was by no means satisfactory as to the state of the patient. He was getting up his appetite, and so far things were favourable; but the time had not yet elapsed at the end of which he might be considered safe. From the 18th to the 23d day of the disease dropsy frequently supervenes, or an effusion into one of the internal cavities of the body: this is said to occur most frequently—I do not know how truly—where the desquamation of the cuticle is slow. The ordinary form of the disease terminates by the cuticle more or less separating; and it is said that dropsy occurs most frequently before it separates: I am not sure, however, that this is a just observation. On the 16th there was heat of skin, the face was very red, the pulse 100, and he complained of much pain in the back, particularly in the region of the kidneys. The urine which he made was exceedingly small in quantity, and very much loaded. I was exceedingly alarmed lest dropsy should supervene, and I had him immediately bled to twelve ounces, and gave him a sufficient quantity of supertartrate of potass to open his bowels freely. Instead, however, of this occurring, as I was afraid it would, the parotid glands on the left side swelled considerably, and likewise the submaxillary glands. Antiphlogistic treatment was used to get rid of this condition: leeches were applied, then an evaporating lotion, and the bowels were kept steadily open. Under these means this has disappeared: the patient still made little water, however, and I was afraid lest dropsy might supervene; I therefore kept him upon diuretic medicines, and ordered him a nitre draught, consisting of fifteen grains of nitrate of potassa in an ounce and a half of mint water, with a drachm of spirits of nitric æther, and twenty drops of tincture of squills. His urine was still loaded, and depositing a sediment. To-day his tongue is clear, and getting better. This is a good and instructive case as to what may occur in what was originally a very mild form of the disease.

I am rather inclined to think that there is in the present epidemic a mixture of disease of the parotid glands with scarlatina. I was called to see a gentleman last week at a large school, who had scarlatina; and since he has had this complaint, a number of the boys have had mumps—a swelling of the parotid glands. I have seen another case, where two children were ill, one with scarlatina, and the other with a swelling of the parotid glands,

immediately succeeding the fever. As this occurrence is not very common, I am inclined to think that there is, as I have said, a mixture of the diseases, so that scarlatina is more likely to be followed by a swelling of the glands than in an ordinary epidemic. Our patient has got quite well of this, but I still fear lest dropsy should come on.

This leads me to say a few words upon the effusion which takes place in this affection. It is remarkable that in Dr. Forthergill's work on Angina Maligna, the disease which attracted so much attention in 1717, no one case is stated to have terminated in dropsy. In every case which I have seen of dropsy after scarlatina, the latter has been mild. A case occurred in this hospital some years ago, of a woman who had a still milder case than the present. She had been well of the complaint more than a week, and was merely kept in as a matter of precaution. Sudden effusion took place into the brain; she was bled; a blister was put on the top of the head, and kept open by mercurial ointment, calomel and diuretics being given at the same time. She was treated briskly antiphlogistically, and recovered. The effusions which succeed scarlatina are generally more troublesome than those which occur in ordinary diseases, or are the result of other affections. I saw some years ago, the case of a child in Regent's Park with scarlatina. The case was mild, and the child recovered. There were two other children, and they were sent into the country, and the house painted from top to bottom. At the expiration of two months they returned, and ten days afterwards, which is about the period of the disease lying dormant, they both took the complaint. One of them was five years old. The case was mild, and the eruption passed off. Suddenly, on the eighteenth day, dropsy came on, and there was anasarca, to a greater extent than I ever saw it in any other individual. The eyes were perfectly closed, and I should compare it to a blown-up pillow-case: there was no appearance of a child. This shews that it is no trifle where it does occur; but happily, from the treatment pursued, dropsy does not very frequently appear. Writers have laid too little stress on this subject. The best description of dropsy supervening on scarlet fever was in a work published by Plenciz, a German physician; and this was afterwards improved by Dr. Wells, in a paper published in the Transactions of a society for the Improvement of Medical and Surgical Knowledge. I recommend you to read that paper.

It not unfrequently happens that effusion takes place into the brain, sometimes

into the belly, but most frequently into the cellular membrane, and thus causes anasarca.

A great many questions have arisen as to how this particular complaint is to be treated when it succeeds an eruptive disease. It is supposed that it is the result of debility, and some assert that more die of this than of the original complaint. Some think that it has become less fatal in consequence of less stimulants being employed; and most modern writers agree on this point. Purging has been frequently employed in the course of the complaint, and even venesection under some circumstances. I am of the same opinion. I have never seen a case in which stimulation has succeeded. Where the inflammatory symptoms run high, and there is great heat of skin, the best plan is, if the child be not broken down, to take blood from the arm, and subsequently to use those diuretic medicines which act strongly on the bowels—saline medicines, with mercury. If the disease has actually become established, and the child is weakly, recourse may be had to some of those medicines which act on the kidneys: *pyrola umbellata*, joined with saline medicines, appears to be the most beneficial. I have seen the exhibition of liquor potassæ followed with great success in cases where the urine was much loaded: a tea-spoonful may be given three or four times a day, in milk; in general it has produced diuresis. The administration of bitters, with diuretics—such as an infusion of gentian and of digitalis—is a favourable mode of proceeding in some cases. The Germans are of opinion that an infusion of broom-tops is better adapted to this form of disease. I believe, however, that dropsy rarely takes place where the patient has been properly purged. In Dr. Hamilton's work on Purgative Medicines, you will find an account of an epidemic scarlet fever which raged at Edinburgh in his time; and in that epidemic, after the boys had appeared to recover for two or three days, effusion took place into the different cavities of the body. This led him to be careful in examining the reason, and he found that by purging freely as soon as the patients became convalescent, no other cases occurred during the whole progress of the epidemic. Foreigners, particularly the French and Italians, never think of employing cold affusion. When a patient has scarlet fever, he is shut up in a room, and ordered to be kept in that state forty days: not an atom of air is allowed to enter; and if the patient then has no anasarca, he is considered to be safe. It is almost like treating a person after the plague. Many years ago, I attended two

children in Italy labouring under scarlet fever. I ordered the windows to be left open, and cold water applied, in the month of November. The effect was astonishing to some medical men. The patients recovered perfectly, and no unfavourable symptoms took place. In fact, dropsy, I believe, will not occur where the inflammatory symptoms of the disease have been treated during the complaint. Besides, there is another consideration. Almost all eruptive diseases, if left to themselves, terminate by diarrhoea; and if this is kept up by medicine towards the end of the complaint, all goes well. But if patients are not purged, and diarrhoea does not come on, then it is reasonable to imagine that the vessels will pour out fluid into the different cavities of the body. You are therefore to attend throughout the whole course of scarlatina to keeping the bowels freely open; and where the inflammation runs high, it is to be treated like any other inflammatory disease. The severe form of the disease, although not common, is an inflammatory disease, and is not followed by those sequelæ which occur in the milder form of the complaint.

But there are cases of scarlatina in which it becomes necessary to stimulate the patient from the very beginning of the disease, and in which absolutely there appears to be no inflammatory condition. The patient is taken very ill, and an ulcer forms on one or both tonsils, which is ash-coloured, and the breath is so offensive that you cannot bear to approach him. The inflammation creeps down the windpipe, and the patient dies. At other times the inflammation is of so fatal a character, that the nervous system becomes affected sympathetically, and in that way the patient dies,—just as a malignant disease at a distance produces death under other circumstances. You are to bear in mind, that the mild form of the disease in one patient may produce a severe kind in another. Some years ago, I was called to see a child, over Westminster Bridge: it was then at the breast, and laboured under scarlet fever. Nothing could be more mild than the complaint. There was a little efflorescence, and a little difficulty in sucking, but it soon passed off. Eight or ten days afterwards, the mother was attacked with rigors; vomiting and headache came on; and this was followed by great prostration of strength. A purple eruption came out on the legs, and she was much depressed. The throat was dreadfully ulcerated, so that the mouth could scarcely be opened, and the smell was hardly supportable. The patient was ordered three or four grains of sulph.

quinine, dissolved in as little water as possible, on account of the difficulty of swallowing, to be taken every three or four hours, and as much wine as could be got down: indeed she could not have swallowed a great quantity. The woman was by this means raised up from her state of depression, and eventually recovered. I have no doubt that such cases may occasionally occur. Ammonia has been recommended under these circumstances, but the difficulty is to administer it. There is no question but that though scarlatina is an inflammatory disease, yet cases do occur where there is no inflammation, and the impression on the nervous system is so violent, that, if stimulants be not applied, the patient will die during the progress of the complaint. Cases, however, sometimes recover very rapidly. The nurse to whom I alluded presented one of the worst cases I ever saw. A considerable quantity of quinine and wine was given, which cured the complaint; erysipelas then came on; the same remedy was used for the second disease, and the patient recovered.

With regard to the contagious nature of scarlatina, I apprehend there can be no sort of doubt on that question. You will frequently be consulted on this subject, and it is a matter of great importance to know how to reply. It is believed in the profession (and I entertain the same opinion), that a patient labouring under scarlatina, however modified, may spread the disease to another person at any time within a month from the period of attack. Consequently a boy should not be returned to school, or placed with other children, till that period has elapsed. You will remember the cases which I mentioned at Regent's Park, where the children were sent away, and the house painted throughout, and yet, upon their return, in ten days both the children had the disease. In the great majority of instances this will not take place: the children might be returned, and no one would imbibe the disease; but in some instances they would, and you are called upon to guard against such a circumstance in every possible way. You should not advise the child to be returned to the society of other children until a month has elapsed from the commencement of the complaint.

PURPURA.

There is a case in the house of what is termed *purpura*. The patient was with us before; he was relieved, and went out, but has returned. The case is in progress, but the patient is very ill. I shall speak of it at our next meeting, and state the reasons which induced me to employ the practice I adopted.

GOUT.

One of the gouty patients has had a slight return of the affection, but, upon the whole, the case is doing well. The two other patients are ready to go out whenever I think proper. I have no doubt that the slight return will be removed by the same means as before.

EPILEPSY.

I spoke, in a former lecture, of two cases of epilepsy: one case was attributed to a fall, and a seton was placed in the neck. Since that time the patient has had one fit, but it is now several weeks since, and he is going to be dismissed. The other is the case of the boy who has epilepsy once a month. We have verified this by the case; because I kept him in, that we might see he was not deceiving us. I put him on arsenic, and increased the dose to six drops of the arsenical mixture three times a day, as he approached the period when he expected to have a fit. Whether it will come on, I cannot say; but the charm is destroyed, for the period has passed by two or three days, and consequently we may hope that the chain of action is broken which constituted the disease. I mentioned that the best way would be to put him on arsenic, and so far as the case has gone it appears to be successful.

ST. GEORGE'S HOSPITAL.

Case of Poisoning with Hydrochloric Acid.

JOSEPH GOODMAN, æt. 25, cabman at Chelsea, admitted, under the care of Dr. Chambers, October 31st. Pulse 58, small; skin warm; tongue much excoriated, dry.

He was reported to have taken about ℥ij. of hydrochloric acid nearly two hours before he was admitted into the hospital. He had vomited some dark greenish matter, which effervesced with carbonate of soda. About ℥iij. of this were then administered to him, with mucilaginous drinks and linseed tea. He did not himself think that he had actually swallowed much of the acid.

R Magn. Ustæ, gr. xv.; Mucil. Acaciæ, 3iss.; Aq. Distill. 3x. 4tis horis.
Enema emolliens, 6tis horis.

Hirud. xvij. gutturi et postea. Cataplasma Lini. Fetus abomini. Fever diet.

He vomited once or twice in the course of the night some dark matter.

November 1st.—Pulse 180, rather sharp; bowels not open; tongue dry; complains

of much soreness about the throat and fauces.

V. S. ad 3xviiij . Enema Ol. Ricini.
Vespere repetantur Hirud. xx. gutturi.
Ol. Ricini, 3iss . cras mane.

2d.—Symptoms somewhat relieved; throat less sore; no sickness; no pain in abdomen. Pt.

3d.—Pulse 85, rather sharp. Tongue healing, not so dry. Throat very sore.

R Decoct. Cydoniæ, 3iss . Mell. Boracis, 3j . M. ft. Garg. sæpe utend.
Hirudines xij. gutturi.

4th.—The sickness has returned, and he has vomited some dark-green matter. There is this morning some slight pain in epigastrium on pressure.

Hydr. Submur. gr. ij. ter die.

5th.—Sickness has rather abated, and there is scarcely any pain in the epigastrium. Throat less sore. Pt.

6th.—His tongue is much swollen, so that he can hardly protrude it. He complains of his throat being very sore, with pain extending downwards to the left side of his chest. There is a slight erysipelatous appearance on the nose.

V. S. ad 3xij . H. Salinus c. V. Ant.
Tart. 3ss . c. singulis Pilulis sumend.

7th.—Pulse full, soft, frequent, regular. Tongue much swollen and dry; has great difficulty in swallowing. There is much pain in the left side of the chest, with some palpitation and giddiness. There is strong action of the heart, but without bruit. He had some shivering this morning. The patch of pale erysipelas on the nose had nearly disappeared, but has now returned. Blood drawn yesterday much inflamed.

C. C. reg. cordis ad 3x . Decoct. Cydon.
Aq. Rosæ aa. 3iij . Mell. Boracis, 3sa .
Ft. Garg. Rep. Pil. et H. Salinus.
Milk diet.

He fainted after the cupping, but soon afterwards rallied. In the evening he was seized with great difficulty of breathing, but without much pain either in the chest or epigastrium, and till the last complained only of his throat.

He died on the 8th, about $1\frac{1}{2}$ A.M.

Post-mortem.—On opening the chest there was found in the right cavity of the pleura about Oss. of serous fluid, mixed with blood; and in the left about Oj. of the fluid, with shreds of lymph floating in it. There was some inflammation of the larynx, and this increased as it descended into the bronchial tubes. The left lung was much inflamed and condensed, and purulent matter exuded from the cut

edges of the small branches of the bronchial tubes. In the pericardium there were about 3ij . of fluid. The tongue was much inflamed and enlarged. The œsophagus was highly inflamed; and in some parts the mucous coat had sloughed, and in others it was rather thickened. The coats of the stomach were very highly inflamed, and in most parts had sloughed; and large dark shreds of the slough were hanging from its sides, especially about the pylorus. The inflammation had extended into the duodenum, but no sloughing had taken place there.

The liver, pancreas, kidneys, and heart, were healthy.

ASSISTANT-SURGEONS IN THE NAVY.

MANNER IN WHICH THEY ARE TREATED.

To the Editor of the Medical Gazette.

SIR,

I THINK you cannot be aware of the manner in which medical affairs are conducted in the navy, or your attention would long ago have been directed to the subject. I am inclined to think so from the temperate and straightforward course you have always pursued—giving praise where praise is due, and never shrinking from the duty of exposing abuses where *real* abuses exist. It is with this sense of your impartiality that I am induced to bring before your notice, and that of the medical profession, facts which I fear have hitherto been kept too secret, and not proclaimed with that truth and publicity which their importance demands. Whether this supineness results from the aggrieved party being absolutely so ashamed of their condition as to prefer privacy, or from other causes, I know not; but this is certain, that no proper means have yet been adopted to remove the grievance, either by the actual sufferers, or by any other parties.

The surgeons and assistant-surgeons of the navy both labour under great disadvantages, and are even now far behind their brethren of the army; but it is to the condition of the assistant-surgeon that I particularly wish to draw your attention, because it is the most glaring and most degraded. The state of the surgeons is tolerable, nay respectable, but that of their assistants is altogether degrading.

Those who enter the navy are for the most part young Scotch physicians, who, having finished their education, enter the

service with a false idea of its being a convenient place for study, and prosecuting practically their favourite sciences on foreign shores. But, alas! how many unfortunate young men, when too late, have discovered that these notions were preconceived and erroneous—that their hopes were merely the fictions of their own ardency, and that they have, heedlessly and unadvised, taken a step totally inconsistent with their previous habits and education. Such a one, perhaps, has “interest” in the navy; he is young, and full of hope (not to mention dazzled by a fine uniform, which is very natural); he has a laudable desire of visiting distant shores, his previous education having taught him to behold them with a scientific eye; he is anxious to witness and to investigate the causes of natural phenomena, the productions of remote climates, both geological, zoological, and botanical: all these glowing inducements decide his doubting mind. He is consequently appointed to a ship; he is no sooner embarked than his troubles commence; he is conducted to the midshipman’s berth, and learns that these boys are to be his future messmates and companions, together with a few petty officers,—as the coxswain, carpenter, &c.; he has to sleep in public!—it is a fact; he has no private cabin, though the carpenter and others have this convenience. To read is out of the question; if he attempt it, his books are torn and otherwise ill treated: indeed he seems to be singled out as an object of degradation and contempt.

Now what is the consequence of all this? Why look to the poor suffering officers themselves, and read the melancholy answer; see how necessity triumphs over education and all moral restraint—how they acquire the habits of their associates, and daily lose more and more of their previous acquirements, till at length they become unfit for promotion. The truth must be spoken, sir, however painful the intelligence may be; for the surest way of curing a malady is to ascertain its extent. I need scarcely observe how the evil extends beyond the actual sufferer—how it implicates the whole medical profession; for surely no insult can be offered, or degradation heaped upon any portion of a profession, without its being felt, in some shape or other, by the whole brotherhood. But it is not so much to the personal inconveniences that I allude (which, in truth, are bad enough), as to the impolicy, the cruelty, of placing these officers in a situation to which they are totally unsuited, both from the nature of their professions and the studious habits which they have, or ought to have. It is all very well for boys who are learning navigation and the

duties of a naval officer; indeed, in such a case it is indispensable, for they must of necessity be separated from their superior officers, to keep up that distinction which a more intimate intercourse would destroy; for, as boys, they could not appreciate such intimacy without losing that awe which must exist between the two;—but with the assistant-surgeon it is quite otherwise; he has already gone through the drudgery of his own profession, and his sole object now should be to retain what he has acquired, and direct it in proper channels; and until suitable opportunities are afforded him to further these objects, the naval service will ever want that degree of medical skill which her peculiar circumstances demand. After duly considering this subject, I am convinced there is only one remedy for the evil, and until that be adopted there can be no hopes of improvement among this class of officers. He should be admitted into the gun-room, and to the society of its inmates; a claim to which he is entitled by all the rights of humanity and justice—a claim which the respectability of his own profession demands—a claim which science calls aloud to be satisfied; and I cannot but think that those who stand in the way of its adoption, are accumulating a heavy load of responsibility on their own heads; and, oh! could they but see, in one concentrated view, the dark train of evil consequences resulting from their apathy, I am sure they would relent, and give every aid to promote, rather than oppose, this measure.

I might advance many arguments in support of this claim, and particularly dwell on that which relates to the obstacles of scientific pursuit, and its consequences; but I know that your time is much occupied at this crisis of medical science, in turning aside the revolutionary flood which is setting in, and swelled too, by the efforts of her own members. We must acknowledge that you have a task which requires undivided attention; nevertheless, I entreat, in behalf of the unfortunate sons of that profession, who are now rolling on the sea under a tropical sun, that in the midst of your exertions you will not be unmindful of *their* sufferings; they are scattered far and wide on the bosom of the ocean, and therefore cannot come before you with clamorous complaint: their silence may be mistaken for contentment or resignation, but I fear it is the sullenness of wounded pride.

I remain, sir,

Your obedient servant,

W. M. B * * *

November 24, 1836.

NERVES OF THE ORBIT.

NOTE FROM MR. SHAW.

To the Editor of the Medical Gazette.

SIR,

I AM unwilling your readers should think that, in noticing the error committed by Mr. Thurnam, I expressed myself in a manner calculated to warrant the belief that I was "wanting in good feeling." I should be very sorry if it were considered that I took advantage of this gentleman's having fallen into a mistake (of which, indeed, there could be no question), in order to make my observations more severe than his negligence really warranted, or that I was actuated by any improper feeling. Permit me to remark, that in deprecating my supposed want of good feeling, Mr. Thurnam forgets that, by his own carelessness, he had laid himself open to a worse charge than I brought against him, that of wilfully committing an act of injustice towards another. His last letter shews how his mistake originated; and I take this opportunity of saying, that if I had been aware that the early paper to which he referred did not contain the views relative to the sixth nerve, which have been the subject of our discussion, I should have given him the advantage of this circumstance, and have explained his error in such manner as not to have caused him the least pain.

I have the honour to be, sir,
Your obedient servant,
ALEXANDER SHAW.

Middlesex Hospital School,
Nov. 28, 1836.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

November 17, 1836.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XI.

Further remarks on the Evidence of Rape—Violation without defloration—Appearances in prostitutes—Possibility of the proofs in married women—Miscellaneous considerations—Ages of the parties—Violation of infant children—Evidence from certain discharges—Distinctive characters of menstrual fluid—Pregnancy in reference to rape—Question of consent—Sham cases—Practical rules for investigating cases of rape—Report in illustration.

In the last lecture I treated of some of the chief circumstances connected with rape—a subject of high importance in Forensic medicine; as will readily be admitted, when we take into consideration the frequency of the charge, the difficulty of the proofs, and the doom that awaits the convict.

General evidence in cases of rape.—"The accusation," says Lord Hale, "is easy to be made, and harder to be proved; but it is harder to be defended by the party accused, though innocent." And in another part of the "Pleas of the Crown," this learned Judge notices particularly the precariousness of the evidence of the crime: it presents, he says, "the greatest difficulty; wherein many times persons are really guilty, yet such an evidence as is satisfactory to prove it can hardly be found; and on the other side, persons really innocent may be entangled under such presumptions, that many times carry great probabilities of guilt."

471.—XIX.

In cases of this kind the primary evidence is generally given by the complainant herself; her single testimony is adduced in proof of the fact, and she is held to be a competent witness, (even the wife against the husband—as in Lady Castlehaven's case, 3. State trials, 411) provided certain moral circumstances concur to attest her credibility. She must be a person of good character, must have denounced the offender without loss of time, and be able to show that she made all possible resistance. But, on the other hand, it deserves to be noticed, that even though she be of bad character, and have concealed the injury for some time after she had an opportunity of revealing it, and although it does not appear that she made any outcry at the commission of the offence, still her testimony is not to be wholly rejected.

Medical evidence.—Among the collateral facts, proof of which is requisite to support the general accusation, marks of violence on the person, and especially about the sexual organs, must be clearly made out. The circumstances should be very peculiar, indeed, to justify a conviction for this crime, without any appearances indicative of violence being detected about the complainant's person. Hence the necessity of medico-legal interference.

I have already observed that the crime of rape is usually distinguished by the medico-legal authorities, (the legal make no such distinction) according as it is committed on those who have had, and those who have not had, sexual intercourse before. Consistently with this arrangement, I noticed in last lecture the signs of forcible deprivation of virginity; and it remains to offer some remarks on the proofs of rape that may be looked for in other females than those who have been recently virgins.

Violation without defloration.—The common impression is, that if it be difficult to detect the fact of violated chastity in the

young and unmarried, it is infinitely more so—more truly like exploring “the way of a serpent on a rock,” when the person to be examined is differently situated. We should recollect, however, that by far the greater number of alleged rapes are attended with brutal violence; and if we may credit some excellent authorities, the difference between the used and the unused is not generally so great as to make a material alteration in the indicia of sexual injury, especially if it have been excessive.

Even in the case of prostitutes it does not appear that the difference is very observable. I shall here make an extract or two from Parent-Duchatelet's volumes, (*De la Prostitution dans la ville de Paris*) already quoted, a work which abounds with facts the most extraordinary—at the same time, I believe, the most authentic. “If there be one opinion more generally received than another, it is that the genital parts of prostitutes *must* present appearances and alterations inseparably connected with their occupation: it is the common talk of libertines, high and low, young and old, and a standing joke when any of the associates of the latter happen to marry women who had formerly been on the town. I have even found medical men themselves more tinctured with the popular notion on this head, than the common orders of society. . . . In order to obtain exact information, I applied to all the most likely sources—to the dispensary physicians and surgeons, to those attached to the hospital of the police, to the prison infirmaries, and, in fact, I allowed no opportunity to escape me. The results are precious, and shall be concisely stated.

“There is *no* special or peculiar change observable in the sexual parts of prostitutes; no difference, indeed, between them and the most respectable married females. The frequent use of the speculum, and the other methods employed in examining women of the town who apply at the dispensaries, as well as those leaving the hospitals and prisons, have convinced the medical inspectors that largeness and smallness of the vagina are merely natural and congenital conditions, no more remarkable than the disproportion which is commonly met with in individuals as to the size of other parts of the body. Young prostitutes are frequently met with just commencing their trade, and who have never been with child, yet having the vagina more dilated than is found in married women who have had five or six accouchments; while on the other hand, we may observe women who have been on the town for twelve or fourteen years, nay, who have decrepitude stamped upon them, yet whose sexual parts, and particularly the vagina, exhibit

no trace of alteration. There was a woman pointed out to me one day in the prison of the Madelonnettes; she was 51 years of age, and had been for *fifteen* years a prostitute in the metropolis; notwithstanding this, her sexual parts might have been confounded with those of a virgin at puberty.”

Appearances in married women.—The statement of these facts is most important as regards the possible proofs of rape in married women, or those who have avowedly had previous sexual intercourse. With the exception of absence of the hymen, it is possible that such women may have had, anterior to the violence offered them, all the appearances of uninjured chastity, and consequently whatever marks of violence of a recent nature are present, may reasonably be attributed to the alleged outrage. It is an unreasonable as well as an uncharitable doctrine to hold, as some do, that appearances of this kind in married complainants must be looked on with suspicion, as indicating that methods had been taken to produce aggravated lesions, by way of having a stronger *corpus delicti*. Why may not the marks of brutality be observable in such women, as well as in others—especially if we admit the correctness of the remarks of Parent-Duchatelet and his informants? And is not the contrary persuasion founded in that very vulgar error which these authorities have exposed?

Great caution undoubtedly ought to be observed in gathering the proofs in such cases; but so ought it in every case, whether relative to the unmarried or the married. Some have suggested that more evidence of proof should be required in respect to the married than the other; and it has been even proposed that, however the fact of penetration may be deemed sufficient in the latter case, proof of *emission* should always be insisted on when a woman who has avowedly had previous connexion is the complainant. I cannot help thinking that this suggestion is founded in bad physiology; for it assumes a position for which there is not sufficient warrant, that women are always sensible of the occurrence when emission during the generative act takes place. And if this be so when there is no mental disturbance, how unreasonable to expect that a female should attend to such an event when she is made the victim of outrageous and brutal assault! To demand proof of emission from the married, is as unjust and as absurd as to require rupture of the hymen in proof of penetration in the unmarried; for in both instances what is this else than to “contend that more is necessary to constitute rape in law than generation in nature?” For without either perception of

emission, or penetration into the vagina, impregnation may be effected; as in fact the same learned authority I have just quoted says, "the utmost wrong to one party, and the malignant intent of the other, may have been complete; while injury on the one hand, and malice on the other, are truer criteria for administering justice than the dicta of lawyers, and the etymologies of schoolmen."

I have dwelt upon these points chiefly with a view to remove those impressions which are prevalent, more particularly if you should happen to entertain them, that there is little or no use in examining the persons of females complaining of rape who have had previous intercourse. With ordinary caution, it may be done, I think, with more confidence than is usually supposed; and although we shall find no laceration of the hymen, yet the other signs may in great measure be expected to be present: we may find bruises, red spots, and excoriations of the sexual parts, such as would be produced by the introduction of a foreign body; a sort of mucus may be detected about the parts, which may prove to be seminal fluid; and, lastly, ecchymoses or other marks of injury may be observed on different parts of the body. When such appearances are seen, the probability of the alleged violence must be considered strong; and the presumption will be admitted to be greatly strengthened when it is borne out by moral and collateral circumstances, such as have been already alluded to—namely, the timeliness of the complaint, the solitariness of the *locus in quo*, with the impossibility of obtaining assistance there,—and, lastly, the general demeanour and conduct of the woman.

Miscellaneous Considerations.

Age of the parties.—The present law of rape seems to be of dubious application in other respects beside those already noticed. I mentioned in the lecture on Age, that boys under *fourteen* are presumed, in law, to be incapable of the crime of rape, evidently with the idea that emission is essential to the act. But by the late statute making the essence of rape consist in penetration merely, the commission of the crime, wholly independent of the hypothesis of precocious puberty, is obviously within the powers of very youthful delinquents. Mr. Chitty notices this circumstance, and seems to think that some alteration of the law would be expedient: "perhaps a different rule might without impropriety be adopted, so as to include offenders of an earlier age than *fourteen* (who are between that age and seven, legally capable of committing other

crimes). Yet," he adds, "as the law has once fixed that age as the earliest time when the ability to commit a sexual crime is to be considered as established, it is most probable that the rule would be still adhered to, although one of the reasons for its adoption has ceased."

With respect to female infants, the law is strict in yielding them protection under certain ages; they are presumed to be incapable of giving consent under *twelve*, and it is a capital felony, under any circumstances, to have carnal knowledge of a child under ten. The act formerly referred to (9 Geo. IV. c. 31) says in the 17th section,—"that if any person shall unlawfully and carnally know and abuse any girl under the age of ten years, every such offender shall be guilty of felony, and being convicted thereof, shall suffer death as a felon; and if any person shall unlawfully and carnally know and abuse any girl, being above the age of ten years and under the age of twelve years, every such offender shall be guilty of a misdemeanor, and being convicted thereof, shall be liable to be imprisoned, with or without hard labour, in the common gaol or house of correction, for such time as the court shall award."

Yet cases of this criminal nature are not infrequent. Scoundrels, particularly in low life, entertain an idea that the remains of a venereal affection, such as gonorrhoeal discharge or gleet, may be got rid of by a sexual intercourse with a healthy female; and an infant under the age mentioned in the act is preferred, as not likely to offer much resistance. The following are instances of this insatuated guilt, and they may serve to shew how the law deals with such malefactors.

At the Norwich Spring Assizes this year (1836), Robert Bunting was indicted for a rape committed on Phoebe Taffs, a child only four years and a half old. The case, it appears, was *fully proved*, but the evidence was deemed unfit for publication. The child died of the injuries received from the violence of the prisoner. The prisoner was sentenced to death, without hope of respite.

In June last, a man of the name of Kinsey was tried at the Old Bailey, for violating the person of a girl under nine years of age. He was found guilty, and sentenced to death; but has since been transported for life. According to the brief report of this case which I have seen, the child did not complain until six weeks or two months after the "outrageous" act (as the Recorder termed it); yet the surgeon who gave evidence was able, from inspection of the infant's person, to speak positively as to the commission of the

crime. This would seem to warrant the supposition that gonorrhœa or venereal disease was communicated to the child, which led to the detection of the prisoner's guilt; and probably the injury done to the sexual parts might have been sufficiently serious to leave its traces even after that lapse of time.

Discharges. (a.) Supposed venereal.—When violation is effected with the notion of getting rid of some venereal complaint, it is very probable the malady may be communicated to the victim. But great caution must be observed in judging of this fact: the nature of the discharge, if there be one present in the complainant, must be carefully ascertained, the appearances of violence on the surrounding parts must be noted, and the time should form a material element in our estimation of the probability that the disease originated in the manner alleged. Some well authenticated cases are on record, which should serve to warn us of the mischief that may be done, if the true state of the complainant be not deliberately and wisely investigated. Dr. Percival mentions a remarkable case of a little girl, only four years old, who was attacked with mortification of the sexual parts, attended with great soreness and general depression of strength. She had slept with a boy of fourteen, and it was suspected that he had taken criminal liberties with her. The mortification increased, and the child died. The boy was presently apprehended, and tried at the Lancaster Assizes; but was acquitted on evidence being given that several instances of a similar disease had appeared in other children, about the same time, in which there was no possibility of injury or guilt. In one of these cases the body was opened after death. The disorder had been a typhus fever, accompanied with mortification of the pudenda. There was no evident cause of this extraordinary symptom discoverable on inspection: the lumbar glands were dark-coloured, but all the viscera were sound.

Capron relates a case almost identical, in which he had the utmost difficulty in convincing the parents of a little girl, only four years old, that they were in error. The child had great swelling of the sexual parts, with pain and purulent discharge; and it was attributed by the father and mother to some impure venereal contact or violation. But the medical examiner shewed them that a similar catarrhal affection of the sexual organs prevailed epidemically about this time; and by the use of some simple remedies the child was cured.

The same authority mentions his having met with a case in the year 1809, where

the presence of a most acute leucorrhœa, in a child of six, would certainly have persuaded the parents that it originated from a venereal commerce, had they not been more reasonable than in the preceding instance. It was nothing more than a catarrhal disorder of the uterine system, proceeding from the cold and moisture of the weather, and owing in great measure to the want of sufficiently warm clothing on the little patient.

Venereal in reference to rape.—It has happened in some instances that, after an alleged violation, the complainant describes herself as infected with gonorrhœal discharge, or chancre; and this has been found to be the case. But how does the fact of communicated venereal bear on the charge of rape? We must recollect what time usually elapses after an impure connexion, before chancre or gonorrhœa is perceived. Three days may be about the average period; and it will be for the medical examiner to form an opinion, from the appearances, how long the complainant may be actually labouring under the disease. Above all, he must be perfectly satisfied that it really is venereal. Now suppose a woman with incipient gonorrhœa or chancre to bring a charge of rape against a particular person; it will readily be seen that the case cannot be very recent, nor should the marks of violence about the sexual organs be expected to be very striking, if, indeed, they should be at all visible. On the whole, the presence of venereal in the complainant can scarcely be considered as an accessory proof of rape, unless it coincide in every respect with the other lesions observable on the sexual parts; and unless the accused party labour under similar venereal disease.

(b.) Supposed semen.—A gross error committed by a medico-legal examiner has been pointed out with strong censure by M. Orfila. The examiner in question was called to inspect the person of a girl, under the age of fourteen, who was said to have been violated *nine days* previously: he considered the appearances conclusive that copulation had been effected, and one of his proofs was, that he found a quantity of *semen* in the vagina! Orfila, who was consulted subsequently on the correctness of the report, shewed that this statement of the discovery of seminal fluid was most improbable. The girl, it appears, had a mucous discharge from the part, which must have carried away any sperm that might possibly have been deposited in the vagina *nine days* before. At all events, the broad assertion that the fluid found was semen, was wholly unwarrantable; for it does not appear that any attempt was made to shew that it was not

mucus: no chemical, no microscopical experiment was tried; and on the whole, did it not appear that the examiner was not aware of the serious nature of his statement, so rash an opinion would have justly cost him his professional reputation.

(c.) *Menstrual discharge.* — Great stress is sometimes laid on the discharge of blood said to take place in consequence of forcible defloration. But there is nothing in this positively indicative of the defloration being forcible; it may occur in a first or other intercourse, even with consent. Besides, we should distinguish, if possible, between an alleged hæmorrhage and the menses. In the former case there should be evidence of laceration of the hymen or nymphæ, or rupture of some of the vessels belonging to the genital organs. In the latter we may be guided by circumstances, as well as by the physical characters of the menstrual discharge. If there be no apparent rupture of parts, and the fluid be traced high up into the vagina, there is a probability that it is the menstrual flux proceeding from the uterine vessels—a presumption which will be corroborated by the distinctive appearances of that fluid.

The menstrual flux, though it has been traced to the vessels of the uterus, has hardly any common property with blood, except that of being a liquid of a red colour. It is chiefly distinguished by its not being coagulable; and hence, when coagula are found in it, as in laborious or profuse menstruation, blood is certainly intermixed. "It is," according to John Hunter, "neither similar to blood taken from the vein of the same person, nor to that which is extravasated by accident in any other part of the body; but is a species of blood changed, separated, or thrown off from the common mass, by an action of the vessels of the uterus similar to that of secretion; by which action the blood loses the principle of coagulation, and, I suppose, life." Other observers have since confirmed these views, by finding that the menstruous fluid differs from blood chiefly in containing little or no fibrine. And another character, in addition to its non-coagulability, has been attributed to it—namely, that it is not acted on by exposure to the air, as venous blood is, which it chiefly resembles. "If a cloth be steeped in blood as it flows from a vein, the colour will be observed to become brighter by degrees: but this is not the case with the menstruous fluid; it retains its dark colour however long exposed*."

But it must be confessed that we are still in want of a good analysis of the menstrual fluid. The only account of its chemical qualities which I have been able to meet with is that given by Gmelin, in his *Handbuch der Chemie*, consisting of two cases which he takes from other journals. In a woman who had prolapsus uteri, the menses were examined: they contained no globules, were green by transmitted light, and resembled a strong solution of the colouring matter of the blood in serum.

In the other case, where the fluid had been retained for some time by an occlusion of the vagina, it appeared as a thick, glutinous, brown-red syrup, without any smell; three days' exposure to the air produced no change in it; there was no deposit (or coagulum), nor any approach to putrefaction; it was liquified by potash, and thickened by sulphuric acid and alcohol; water, in which it was immersed, took very little of its colour, but subsequently became clouded in evaporation, and as if coagulated on the addition of alcohol.

Pregnancy in reference to rape.—It was at one time a matter of great importance to ascertain whether a woman who complained of rape would prove with child: if she did, it was assumed that she must have given consent, and her charge of violation fell to the ground. It was even customary to stay the execution of the convicted ravisher until the question of pregnancy was determined. But a more sound physiology has dissipated this error; and it has long since been ascertained, that, so far from consent being essential to conception, complete insensibility—nay, agony, hatred, and the most violent struggles of resistance—are not inconsistent with a fecundating act of copulation. Of this, however, more hereafter.

Question of Consent. — The point just touched upon, respecting the consent of the female, is one that requires further notice. The legal definition of rape—carnal knowledge forcibly and against the will—sufficiently indicates that this circumstance in the crime must be clearly made out, and, in ninety-nine cases out of a hundred, the question of consent constitutes the chief difficulty. There is, indeed, one case in which a rape may obviously be committed without resistance, and apparently *with* consent: that is, where a violator takes the husband's place, and thus accomplishes his purpose. The crime, however, is not altered in its nature by the deception; for it is inferred that the woman, had she known the vile fraud, would have resisted with all her powers.

Again, there may be no resistance, yet a rape,—where the female is under the influence of some narcotic or intoxicating

* Ramsbotham; MEDICAL GAZETTE, vol. xiii. p. 271.

beverage. Forcible defloration might be, and has been, effected under such circumstances, and a case of the kind excited much public disgust about three years ago,—a Mr. Luke Dillon having seduced from her home and violated a young lady, whom he first brought under the influence of intoxication. But when it is alleged that the crime has been committed in *deep sleep*, the fact is scarcely credible except the female be one who has been accustomed to sexual intercourse. Of the possibility of defloration in profound sleep, we must be permitted to entertain doubts, notwithstanding the decision of the learned Faculty of Leipzig, which held—“*dormientem in sella virginem insciam deflorari posse* ;” nor can one help suspecting, with Valentin, that it must be a fox’s sleep: he shrewdly observes, in his Introduction, in reference to the case, that it reminds him of an old German proverb (*Es schlaffen nicht alle, so die augen zu haben*)—“all are not asleep who have their eyes closed.”

The term *forcible* defloration is commonly employed in the sense of rape, but that is not its exact import: a defloration may be forcible (and it is said that every defloration is more or less so), yet it may not amount to criminal violation. That an extraordinary degree of force may not be inconsistent with consent, we learn from a very shocking fact mentioned by Dr. Ivory Kennedy, in the Dublin Journal, of the whole vesico-vaginal septum being broken down, in a first connubial intercourse!

Sham cases.—Much may be ascertained by the medical jurist, in regard to the question of consent or non-consent. It is in this that the detection of sham cases consists; of which, according to Mr. Amos, there are probably a dozen or more met with on circuit, for every genuine case that comes to be investigated.

By noting the physical powers and moral nature of the complainant, much light may be thrown on the facts. At the Derby spring assizes this year, a lad of the name of Dolman, aged 17, was capitally indicted for a rape on Sarah Baxter, aged 21. The complainant proved to be a coarse woman of loose character, who, as appeared from the evidence, *seduced* the prisoner to the act of sexual intercourse, on a public bridle road. The prisoner was acquitted. On his cross-examination, the surgeon who had inspected the person of the female, and appeared as a witness, deposed, that “he was of opinion, as a medical man, that the woman’s statement, that she had not been intimate with more than one man before, was untrue.”

Some authorities go so far as to hold that no violation can ever take place with-

out some consent on the part of the female; she having it generally in her power to foil her assailant. “It is beyond a doubt,” says Orfila, “that it has been found impossible to violate certain girls, though their arms, their legs, and their heads, were held by three or four persons; and it is well known,” he adds, “how difficult is a first act of intercourse, if the female demurs.” Then comes the old story of the Queen of Navarre and the unsheathed sword. But surely the inference is too positive: a woman with strength of body and presence of mind, has a great deal in her power, no doubt; but if, overpowered with terror and violence, she sink into syncope—if she be labouring under the effect of narcotics, or be made senseless by intoxication, the case is altered; and certainly, as the annals of crime but too well testify, a female may be beset by such a number of savage ruffians as would render all her efforts at resistance fruitless.

Where there is an obvious contrast in the physical powers of the complainant and the accused—the former being a robust strong young woman, and the latter, suppose, an elderly and perhaps a debilitated person—the charge should be admitted with great caution. There is an old epigram, in Bayle, on the subject, which I should quote, but that it is in such antique doggerel rhyme. It supposes the question put to a vigorous young complainant, as to how she could swear that her alleged violator—a feeble old man—had effected his purpose in spite of her efforts. Her reply is, that on any other occasion she could sufficiently protect herself, but that she could not on this, for it was really impossible,—she laughed so much!

An anecdote told by an old French author, in a Treatise on Crimes—the same, in fact, on which Cervantes founded his celebrated judgment given by Sancho in the Island—serves very well to shew the extreme difficulty of violation, when the parties are pretty fairly matched. A young man who was condemned for rape was sentenced to forfeit a purse of money; and he was ordered to hand it over to the complainant in open court. On leaving the dock, however, he was permitted to follow the woman, and recover his purse if he could; he soon found that this was impossible, so violent was her resistance. The woman returned, and complained to the judges; but they, being of opinion that one who could so well guard her money might have as easily protected her virtue in the alleged rape, ordered her to give up the purse.

An attention to the moral circumstances will often settle the question of consent. Mr. Amos cites a case which was tried at Leicester, in which a bailiff was charged

with the capital offence of violating a young woman, in a house where he was stationed as a keeper. The girl was the daughter of the owner of the house, and it came out that the alleged rape was committed early in the night, in the very next room to that in which her father and mother slept. Upon being asked if she screamed, she answered, "No."—"Why not?" "For fear of waking my mother!" In another case which was tried at Derby, the woman was quite positive as to the length of time during which the occurrence was happening. It was ten minutes.—"Are you sure?" "Positive."—"How do you know?" Witness hesitated; question repeated. "I counted."—"How did you count?" "One, two, three, four, &c."—"Did you count sixty, ten times over?" "Yes!"

Even when there has been evidence of screams and resistance, doubts fatal to the issue of the case have been raised, as to the sufficiency of such resistance. "In one instance, in particular," says Mr. Amos, "I recollect the screams of the girl being proved by several witnesses. But she had, in some measure, brought the mischief on herself, by walking with the accused in a solitary place late in the evening; and what had considerable weight with the jury, was, that as soon as the man had accomplished his purpose, the girl said to him, 'Oh, George, there is nothing like a good conscience and a pious life!'"

Practical Suggestions.

I shall conclude this part of my subject by laying before you some rules of conduct which may be servicable in the investigation of rape cases.

1. Take a note of the *time* when you are called in to make a personal inspection; for this may be of great importance in determining the nature of the charge—especially if it should appear that there had been any suspicious delay. And lose not a moment in proceeding to the inspection; for the evidence founded on the appearances will greatly depend on the timeliness of the visit. Furthermore, one of the first memoranda to be taken in investigating the case, is the time at which the alleged violation occurred.

2. Observe the age and general *habit* of body of the complainant. Examine the person cursorily, with reference to alleged bruises, wounds, or lesions, of whatever kind. These are afterwards to be more particularly considered with regard to the mode in which they are stated to have been inflicted.

3. Proceed to examine the *sexual parts*, with special regard to the question of penetration. Notice the general form and disposition of the parts; observe any swelling, inflammation, or discharge about

them; laceration of the hymen, if there be appearances of it: state of the carunculæ myrtiformes; and any contusions or marks of violence about the labia, or in their vicinity.

4. Compare the *general* and *particular lesions* with reference to the probable date and cause of their origin. We must make allowance for the period elapsed since the occurrence of the injury, and take into consideration the constitutional peculiarities of the complainant. Was it during the menstrual period that violation took place? or did she labour under any debilitating or relaxing discharge? In such cases there should be less sign of penetration expected to be present than in others; and consequently it may be more difficult to affirm the fact. On the other hand, mark well whether there may not be *too much* proof forthcoming: whether some of the appearances do not seem exaggerated, or different from what might be produced by the male organ. Recollect that other foreign bodies may have been introduced into the parts, and that pains may have been taken to aggravate what was probably at first only a very inconsiderable, if any, injury.

5. Let such *discharges* as may be present be well observed,—whether they be the result of recent inflammation—of leucorrhœa—of gonorrhœa, &c.: and above all, if called in speedily after the alleged violation, seek for seminal fluid in the vagina, as well as for seminal spots and stains on the woman's garments. These are to be tested by their physical, chemical, and possibly also by their microscopic characters: should such tests be successful, they afford a high degree of probability in corroboration of the fact of penetration by the male organ.

6. Should the individual have died in consequence of sexual violence, her body should be examined most scrupulously: lesions may possibly be detected on the surface; there may be fractures, luxations, substances found in the mouth (introduced perhaps to prevent the deceased from calling for assistance)—all sorts of indications, in short, of recent and violent rape. It is possible, on the other hand, that the post-mortem may lead to an opposite conclusion—that death has rather resulted from some other cause: that the deceased had not been *recently* deflowered—perhaps that she had been a mother.

7. Lastly, examine, if possible, the person of the *accused*; for though we may not be enabled to affirm that the individual whom we inspect has committed the crime, it may be in our power from such inspection to say that he has not. We may find him destitute of the means of effecting penetration, or his structure of parts may be such as to render it highly im-

probable he should have perpetrated the amount of injury alleged. Besides, the inspection of the accused party may throw light on the circumstances in another way: in the case of alleged rapes on infants, it will be important to ascertain whether the accused be not infected with gonorrhœa or syphilis, which would certainly in some degree strengthen the presumption of his guilt. And further: there may be bruises and scratches on his person, denoting the resistance of the woman; there may be spots and stains on his linen also corresponding with those observed about the female. All these points, and many more which will in practice be suggested by the circumstances of each case, deserve your best attention: for though it may not be possible to obtain proof of actual penetration, those minor matters, relating to bruises, scratches, stains, &c., may have the effect of establishing the prisoner's guilt on a charge of *assault with intent to commit a rape*. It is by no means unusual, when the capital charge fails, for the judge to direct another indictment to be preferred, charging the prisoner with the misdemeanor.

A report, taken from Sedillot (*Manuel complet de Méd. Lég.*) may serve as an illustration of some of these rules.

"We, the undersigned, went this day, at eight o'clock in the forenoon, to visit the daughter of M. G., aged 16, who was said to have been violated yesterday evening at ten o'clock.

"Upon entering the chamber, we found the girl in bed, concealing her face. We were told that on the preceding night she allowed herself to be prevailed on, under false pretences, to enter the room of M. D., aged —, who, after making her certain proposals, accomplished his purpose, having previously used violence, and ill-treated her, and threatened her with death. Upon examination, we observed that the girl was sufficiently grown and well formed for her age, but delicate and very timid: she seemed to have previously enjoyed a state of perfect health. We saw on her arms, her chest, and lower limbs, several recent ecchymoses,—some of them were close together, and on the arms indicated the pressure of fingers: on the thighs, they were larger and more apart, where it seemed they were occasioned by the closed fist and the bruises of the knees. The whole pudenda were swollen, and there was a discharge from them of a mucous fluid of a yellowish white colour: the external labia were red, and, as it were, slightly glued together; the nymphæ were tumefied, very red, and presented the appearance of laceration, still bloody, and covered with mucus.

"The hymen was ruptured—its remains were distinct and bloody: the mucous

coat of the vagina, which was strongly marked with rugæ, was inflamed and contused; all the parts were painful; and various red spots diffused over the pubes and the thighs, particularly their upper and inner part, gave evidence of recent violence.

"Having requested to see the dress which Mdlle. G. wore at the time of the alleged violation, it was brought to us. The chemise was stained with blood in several places; and we also noticed certain greyish spots, not very thick, but sufficiently tough, making the cloth stiff, as if it was starched in those places. We moistened them, upon which they gave out a very well-marked spermatic odour; and on putting them to the fire, they assumed a distinct reddish-yellow hue. As we were desirous of leaving no doubt about the matter, we collected a small quantity of it in a watch-glass. It formed flakes and cloudiness in the distilled water which held it in suspension, and which had become alkaline. We then evaporated the liquor, and the residue was of a light brown colour, which, when treated with some drops of distilled water, was dissolved but in part, leaving a yellowish-grey glutinous substance, which disappeared in a solution of caustic potash,—facts which leave not the least doubt in our minds of the presence of semen.

"We therefore hold ourselves justified in concluding—from the existence of the contusions and ecchymoses which we observed, from the above-mentioned state of the genital organs, and from the spots of blood, and of semen, detected on the clothes—that the person of Mdlle. G. has been violated. In which persuasion we affix our signatures to this report.—Dated Paris, 17 July, 1823."

REPORT
OF THE
LONDON COMMITTEE OF THE
BRITISH ASSOCIATION,
ON THE
MOTIONS AND SOUNDS OF THE
HEART*.

August, 1836.

THE Committee of members of the British Association resident in London, charged with the investigation of the motions and sounds of the heart, have had numerous meetings, and performed a con-

* Read at the Bristol meeting of the Association, and communicated to the *MEDICAL GAZETTE*.

siderable variety of experiments on living and on dead subjects, with a view to the ends of their appointment. They have also taken pains to inform themselves of the facts and reasonings published by recent inquirers, and have now the honour to submit to the Section the results at which they have hitherto arrived, together with such particulars of their experiments as they consider necessary to substantiate their conclusions.

Before entering, however, upon the statement of their experiments, or of the conclusions to which they lead, they beg leave to say a few words with regard to the scope and plan of their inquiries, and the spirit in which they have entered on them. The Committee would first remark that, though in their inquiries they did not neglect to take note of any phenomena which might illustrate the action of the diseased heart, yet they have felt it their especial duty to investigate the physiological branch of the subject, and have principally occupied themselves with that part which includes the normal sounds of the heart.

With regard to the general views by which they have been guided, they wish to observe that, in entering upon the investigation, it seemed to them possible, *à priori*, that each sound of the heart might have a single peculiar cause, or several co-operating causes; and, if several co-operating causes should be found more probable, that then some of such causes might be only contingent or occasional, and others constant and invariably present; also upon the supposition of a plurality of causes of one or both sounds, that some causes might be common to both sounds, or that each sound might have its own set of causes exclusively. Keeping in view these several possible *à priori* positions, the Committee made an enumeration of the circumstances attending the heart's action that had been, or might be, supposed capable of producing sound, and endeavoured so to vary their experiments, as to exclude in turn each of those circumstances, with a view to isolate, or at least to bring sufficiently into relief, the essential cause or causes of each sound. To the execution of the plan of experimental inquiry thus glanced at, the Committee have devoted some time during the summer, in the course of which they have had to encounter numerous difficulties, especially from the

want of sure means of destroying the sensibility of the animal, without suspending or greatly impairing the action of the heart. And in this respect they have been much less fortunate than several preceding experimentalists, having in no one of the numerous subjects on which they have operated, been able to continue their observations for a longer period than forty-five minutes, notwithstanding the utmost care to avoid unnecessary loss of blood, and to maintain artificial respiration.

It is proper to add, that the subjects of their observations were in most instances young asses from three to six months old, in apparently good health; and that the mode of preparation was in a few instances poisoning with woorara, in others, stunning by a blow on the head; but in a majority of the experiments the animal was pithed. Other animals were tried as well as young asses; viz. the horse, the dog, and the domestic fowl: but, for various reasons, these trials were not attended with results recommending their repetition.

The Committee consider the most convenient order in which to state the facts in their possession, and their inferences from those facts, to be, to describe first succinctly, and from the notes taken on the spot, such of their experiments as gave available results; then briefly to notice under the head of each supposed or possible cause, such points in the experiments as may seem to the Committee to make decidedly in favour of, or against the claims of each of such possible causes; and lastly, to give a summary of the conclusions which the Committee have adopted from the whole of their inquiries.

Memoranda of Experiments, &c.

To satisfy themselves fully as to how far the sounds might be modified by circumstances, such as the state of the lungs, whether distended or collapsed; the state of the circulation, whether excited or tranquil; and the position of the body; the Committee examined the heart on their own persons under all those varieties of circumstance, and found that when the subject of observation is supine, or leaning a little backwards and towards the right side, the first sound is uniform, dull, and without any considerable impulse; but when leaning forwards, and especially if inclining much to the left side, the first sound is louder and fuller-toned, and accompanied

by strong impulse; they found also that full respiration operated like leaning to the right, or the supine position—by diminishing sound and impulse; while full expiration, like leaning forwards and to the left side, rendered the sounds and impulse more distinct; the former louder, the latter stronger and more diffused. When the heart's action is excited by exertion, they found, as might be anticipated, the systolic sound and impulse at their maximum of tone and force. Moderate exertion they observed to increase the intensity of both sounds,—whereas sudden exertion, sufficiently violent greatly to accelerate the action of the heart, they found impaired the distinctness of the second sound, the first continuing loud, short, and with strong impulse. The indistinctness of the second sound in rapid pulsation of the heart seemed to depend in part on its following so closely on the loud first sound as to be masked by it.

EXP. 2.—The Committee made similar experiments on voluntary muscular contraction, with a view to ascertain how far that act is accompanied by sound. The muscles operated on with best effect were the buccinator, masseter, muscles of the neck and forearm, and of the parietes of the abdomen. And in all those the flexible ear-tube carefully applied so as to prevent friction, yielded sounds more or less striking; but the most remarkable results were obtained from the last mentioned parts. From the abdominal muscular contractions, sounds of a "systolic" character, if the expression is admissible, in all respects, and as loud as, or louder than those of the heart, were with facility obtained. The sounds were produced by sudden expiratory efforts, made with force and with the mouth closed, and were obtained with the flexible ear-tube from various parts of the parietes. The sound of muscular contraction seems in the case of the abdominal muscles to be exaggerated by the hollowness of the subjacent parts.

At the time the sound was heard, the muscle under observation always felt to the finger tense and hard, but the sound ceased at the moment that the fibres had attained their maximum of tightness and hardness, and was not renewed except by a repetition of the contractile effort after previous relaxation.

EXP. 3.—Subject a young ass, poisoned with woorara introduced into an incision in the flank.

The animal died sixteen minutes after the introduction of the woorara; much blood was lost in opening the chest; the heart was acting at the moment of exposure, but not strongly; its action became

more regular after inflation was made more steadily.

Both sounds were heard with the instrument applied to the great arteries, but the sound with impulse, or first sound, alone was heard on the ventricles.

The heart, when yielding these sounds, could not, the Committee were satisfied, strike against the chest's walls, or any other hard object.

After opening the pericardium the sounds were weaker, but both sounds were heard with the stethoscope applied to the roots of the great arteries. Both sounds were heard also on the great arteries, when a portion of lung was interposed between the instrument and the great vessels. The heart continued to act for forty minutes.

EXP. 4.—Subject a young ass, prepared as the last. Death twenty-six minutes after poisoning.

At the roots of the great arteries the two sounds were distinctly heard, but after the introduction of two curved awls into the arteries, for the purpose of hooking up one lamina of each sigmoid valve, the second sound was wanting, the first being indistinct. On withdrawing the awls, two sounds were heard, and soon after the heart ceased to act, twenty minutes after the death of the animal. At each systole, while the heart acted vigorously, the ventricles felt to the finger as hard as cartilage.

The heart being cut out and plunged in warm salt and water, a slight undulatory contractile motion pervaded the substance of the ventricles and columnæ carneæ, and continued for some time. In this and every other observation, this vermicular or undulatory motion supervened upon the cessation of the normal action of the organ, and never before the organ had ceased to act as a whole.

EXP. 5.—Subject a donkey, 7 months old, which expired 43 minutes after being poisoned with woorara.

The heart just before death was heard with short loud pulsations. When the chest was opened it ceased to beat, and was very much distended with blood. When part of the blood was let out by cutting the pulmonary artery, the ventricles began again to pulsate feebly, but without sound. When the heart was cut out, it presented the undulatory motion, which was increased by immersion in cold water. The two ventricles being opened by cuts at the apex, at right angles to the septum, and the heart being drawn with the apex upwards through water, the laminæ of the mitral and tricuspid valves were seen to close together each time the heart was so drawn upwards through the water.

—Subject a young ass, destroyed by opening the chest the heart acted producing both sounds distinctly. Curved awls were then introduced into the aorta and pulmonary artery, took back the valves, when the sound was replaced by a sucking sound. The awls being withdrawn both sounds were again heard; the animal acting feebly.

—Subject a young ass. A small opening of woorara was introduced into the chest but without destroying life, and the animal was dispatched by a blow on the back.

Acting very quickly and strongly the chest was opened; first sound distinct. The auricles being pushed with fingers into the ventricles, so as to close the auriculo-ventricular valves; first, or impulse sound, only the second sound wanting. On removing the fingers from the auricles both sounds were audible, the heart acted slowly, but yet strongly. The arteries being compressed between the fingers and stethoscope, the first sound only heard, accompanied by a bellows or rasp sound. On releasing the pressure (from the arteries), both sounds again became audible. An opening then made into the left ventricle, a finger was passed through the auriculo-ventricular orifice to the bottom of the ventricle, and the fingers of the right hand being placed under the right side of the heart was compressed between the hands, so as to obliterate the first or impulse sound was still heard by all, but weak.

—Animal a young ass, destroyed by a blow on the head.

The heart at first acted convulsively, as if with great exertion, but afterwards nearly slow for a short time. While its action was quick, no second sound was heard; but after it became nearly slow sounds were heard: shortly after its action became too feeble to be of any value for observation.

—Subject a young ass. Poisoning by introduction of 24 drops of an emulsion of cantharides into the jugular vein proving unsuccessful, the animal was ultimately pithed.

Opening the chest the heart distended as to both sounds, and in action. The fingers were pushed into the auricles, and through the auriculo-ventricular orifices, when a first sound was prolonged by a whizzing sound. Drawing the fingers both normal

sounds were heard. Needles were then introduced to hook up a lamina of the sigmoid valves of aorta, when the second sound was heard by two observers. The pulmonary sigmoids were also attempted to be so treated (the aortic valves being continued under the needle), when two observers heard the two sounds, but not the third observer*.

EXP. 10.—Subject a young ass; pithed. Chest immediately opened, when the heart was acting slowly but forcibly. At first no second sound was heard, but a bellows sound (instead); then a violent action was attended with a single sound, accompanied by a bellows sound, which (latter) ceased as the heart became more slow in action, after which both sounds became distinct; then the arteries being pressed with the finger at their origins, a first sound was heard, with a blowing murmur accompanying, and another murmur following, but no flapping (or second) sound. On removing the pressure (from the arteries), the second sound was heard, and the murmur ceased. Immediately after the systole a flapping or jerking sensation was sensible to the finger applied to the arteries at their roots. The inversion of the auricles was accompanied by a sensation of thrilling in the finger of the operator. The auriculo-ventricular valves were found to act in water after the removal of the heart from the body, closing on its being drawn, apex upwards, through water.

EXP. 11.—Subject a young ass; poisoned with essential oil of bitter almonds.

A small opening was made in the cartilages opposite the heart, when the stroke was perceived and felt by the fingers inside and outside the sternum at the same time, with sound and with considerable pressure upwards against the finger placed between the heart and cartilages. The chest and pericardium were then opened, which latter had a little serum in it. After turning over the animal on its left side, so as to make the heart hang vertically out of the chest, a first sound was heard through the tube applied to the ventricles, but no second sound. The same sound was heard on the right auricle posteriorly, without the second sound: the heart acted in both cases weakly. The tube being applied to the roots of the arteries, gave the same result to one observer—i. e. a first without a second sound. The animal be-

* The Committee were uncertain how far the hooking up of the valves was really effected, owing to want of strength in the needles; they were not afterwards able, as in other cases where curved awls were used, to find the marks of the needles, so as to ascertain the direction in which they had passed.

ing again laid on his right side, the first sound was heard by two observers. Circumstances prevented the third member of the Committee from auscultating during this experiment, which was not repeated.

EXP. 12.—Subject as above, and pithed. Heart acted 33 minutes. On opening the chest the two sounds were heard, the heart acting slowly and with tolerable force.

The auricles were then inverted by the fingers, and the first sound, continued into a bellows murmur, was heard. The murmur was accompanied by a thrilling motion, sensible to the finger of the operator, and synchronous with the impulse. A lamina of each sigmoid valve was then hooked up (with dissecting hooks), when a sound was heard not followed by a second sound; but on removing the hooks, the second sound was again heard. On inverting the auricles again, the chordæ tendineæ of the mitral valve alone were felt to become tense in systole, and lax in diastole. A finger being introduced into the left ventricle, through the auricle, the first sound was heard with a murmur.

EXP. 13.—Subject a young ass; pithed. On opening the chest and the pericardium both sounds were distinctly heard, but feeble.

On touching the arteries in the vicinity of the valves, a sensation of flapping (or jerking) was observed by all, commencing immediately after the systole, and accompanying the second sound.

The awls being introduced into the arteries (so as to hook up the valves), the second sound was wanting. After removing the awls, at first only the systolic sound was heard, but after a short time both were heard by all.

On opening the heart (at the close of the experiment), the valves were found to have been sufficiently hooked up in both arteries.

EXP. 14.—Subject a young ass; pithed. After opening the chest the pericardium was opened, and a thick layer of tow was interposed between the heart and surrounding parts, the heart continuing to act. At first the systolic sound was heard, followed by a bellows murmur; but afterwards the flapping sensation, and second sound, were very distinct also.

The finger being introduced into the left ventricle by inversion of the auricle, was felt to be gently embraced and pushed, as if by a membrane distended with blood. On the right side nothing similar was unequivocally observed. On pressing the aorta or pulmonary artery between the finger and thumb gently, a *to and fro* thrill was felt accompanying the systole and

diastole of the ventricles, and terminated by a flap. The sensation of flapping (or jerking) was felt to be synchronous in the two arteries.

The tension and hardness of the ventricles, during their systole, were very remarkable.

The pulmonary artery being cut across, the first sound was still loud: and the aorta being then cut across likewise, the same result was obtained—viz. a first without a second sound. The heart was then severed from its other attachments, and the systolic sound was still heard distinctly. The heart was then grasped strongly under blood: it continued to contract vigorously, and the first sound was heard (but not loud) with the flexible tube as well as the common stethoscope. The heart was then taken out, and held in the hand of one of the Committee; when the first sound was distinct, but feeble. On opening the right ventricle, the columnæ carneæ were distinctly seen contracting simultaneously with the ventricle.

Such are the particulars of all the more successful experiments of the Committee. With regard to those possible causes of the normal sounds of the heart, which have been investigated by the Committee, the principal of them are as follows:—The first sound has been attributed to,

1. *Impulse*, or the beating of the heart against the parietes of the chest.

2. *Muscular sound*, or the resonance attending muscular contraction.

3. *Collisions of the particles of the blood* against each other, or against the parietes, valves, &c. of the heart's cavities.

4. The action of the *auriculo-ventricular valves* during systole.

5. And the collision of the *opposite interior surfaces* of the ventricles in the same state.

The normal or second sound has been attributed to,

1. *Impulse of the heart against the thoracic parietes*, owing to the rapid expansion during diastole.

2. *An intrinsic sound* attending the diastole, analogous to that which the observations of the Committee prove to attend the systolic action of the ventricles.

3. *Flapping of the auriculo-ventricular valves*, during diastole, against the sides of the ventricles.

4. The *rushing of fluids into the great arteries*, after the systole.

5. The *rushing of the fluids from the*

auricles into the ventricles during diastole.

6. *Sudden tension and flapping of the sigmoid valves* after the systole.

Of the causes to which the first sound has been attributed, the Committee feel it necessary to notice each separately, except the last. With regard to the alleged causes, however, of the second sound, they will feel themselves justified in being less minute; partly to avoid tiresome repetitions, but principally on account of the obvious preponderance of evidence, as the Committee conceive, in favour of the theory last-mentioned.

First Sound.—Valvular Tension.

It is well known that several eminent writers have attributed the first sound to the sudden closure of the auriculo-ventricular valves during the systole. With reference to that question, the Committee have made the following observations:—

1. Inverting the auricles, and passing the finger into the auriculo-ventricular orifices, does not prevent the first sound, though it must prevent the action of the valves. (Exp. 58.)

2. In the experiments just referred to, the action of the mitral valve, as felt by the finger, was of too gradual and feeble a kind to be capable of producing sound; while, on the right side, the tightening of the tricuspid was not strong enough to be sensible to the finger at all.

3. Various instances where the ventricles were treated so as to obliterate their cavities by pressure, and render valvular action impossible, gave, nevertheless, the first sound. (Exp. 6, 7, &c.)

From those facts, the Committee conclude that valvular action is not a cause of the first sound.

First Sound.—Collision in the Fluids, &c.

The following are the facts observed by the Committee, with regard to the alleged sonorous collisions of the particles of blood amongst themselves, or against the parietes, valves, &c. of the ventricles.

1. The obstruction of the auriculo-ventricular orifices, by the fingers introduced by inverting the auricles, does not materially modify the first sound. (Exp. 7, 8, &c.)

2. The heart being pressed between a finger introduced through the auricle to the bottom of the left ventricle, and the other hand placed outside the right

ventricle, continued still to emit the first sound. (Exp. 7 and 12.)

3. The heart being grasped firmly in the hand, after separation from its attachments, and while immersed in blood, gave the first sound distinctly. (Exp. 14.) The pressure in this case must, in the opinion of the Committee, have prevented friction between the opposite interior surfaces of the organ.

4. The division of the aorta and pulmonary artery, and even the extraction of the heart, does not prevent the first sound. (Exp. 14.)

5. The Committee made also various experiments in order to ascertain the power of fluids to produce sound when in contact with solids.

On compressing, by the stethoscope, the gum elastic bottle, filled with water and under water, they could not succeed in producing any other sound than occasionally a bellows-sound. The power of obstructed currents of liquid to produce the various modifications of the *bellows* sound, was further illustrated to the Committee in several experiments on animals, in which pressure of the arteries, partial obstruction of the auriculo-ventricular orifices, and the suspension of the action of the sigmoid valves, were repeatedly accompanied by this phenomenon: the thrill accompanying this sonorous passage of liquids was, in every case, sensible to the finger.

6. To this we may add, that the experiments of MM. Pigeaux and Piorry (*Archiv. gén. de Méd., &c.*) have been repeated by the reporter, in the presence and with the assistance of Dr. Edwin Harrison, and other gentlemen, not of the Committee, but in no instance of several trials was any thing like the first sound produced.

From the preceding facts, the Committee conclude that the normal first sound of the heart is in no degree referable to any collisions of the particles of the fluids amongst themselves, or against the parietes, &c. of the ventricles.

First Sound.—Impulse.

The facts relating to the connexion of impulse with the first sound, that are contained in the preceding experiments, are the following:—In a variety of circumstances, in which it is difficult to see how impulse could occur to cause sound, the systolic sound was distinctly audible—viz.

1. When the heart lay exposed, de-

prived of its pericardium, and supported by the mediastinum alone, as in Exp. 1.

2. When the heart was held between the fingers, with some force of pressure, the left side cavities being empty, or nearly so, as in Exp. 12.

3. When the heart was imbedded in tow. (Exp. 14.)

4. When the heart hung out of the thorax by its vessels, removed from all contact to which sound might be referred, as in Exp. 11.*

5. When the heart was severed from all its attachments, and grasped strongly in the hand, as in Exp. 14.

On the other hand, several facts show that the impulse against the ribs may produce sound.

1. In Exp. 11, and in others, in the memoranda of which the fact has been omitted, the heart, during systole, was felt, both outside and inside the chest, to press with force against the sternum and cartilages.

2. In our observations on the effects of posture, we remarked, that leaning to the left or forwards, gave additional force to the impulse and loudness to the sound; while inclination of the body, such as to cause the heart to gravitate away from the ribs, diminished at once the sound and impulse.

3. To those we may add the facts pointed out by Dr. Spittal, (*Edinburgh Medical and Surgical Journal*) *which have been repeated and verified by the reporter*, assisted by Dr. E. Harrison and other gentlemen not of the Committee, and which seem to prove that if the living heart impinge with any force upon the walls of the thorax, sound must result.

From the whole of these facts the Committee conclude that impulse is not the principal cause of the first sound, but that it is an auxiliary and occasional cause, nearly null in quietude, and in the supine posture, but increasing very considerably the sound of the systole in opposite circumstances.

First Sound—Muscular Tension.

The facts ascertained by the Committee relating directly to muscular tension as a possible cause of the first sound, are few but striking, and in their judgment decisive.

1. The heart in systole becomes suddenly, from a comparatively soft and

flaccid body, extremely tense, and to the touch hard as cartilage. (Expts. 4 and 14, and many others in which the fact was not recorded).

2. The unvarying and uniform character of the systolic sound, however diversified the circumstances in which the heart was placed (Expts. 3, 7, 11, 14), furnishes a strong argument in favour of its intrinsic nature.

3. The voluntary muscles, when suddenly contracted, become tense and hard, and emit sounds resembling strikingly the first sound of the heart. This is especially observable in the action of the abdominal muscles. (Expt. 2.)

4. From these experimental facts, taken along with the self-evident fact, that the muscular tension thus experimentally proved to be sonorous is an essential part of muscular contraction, the Committee conclude that the first sound of the heart is a physical result of the sudden transition of the ventricles from a flaccid condition to a state of extreme tension;—that, in a word, the first sound is essentially a muscular sound.

Second Normal Sound of the Heart.

We now proceed to the consideration of the normal second sound, and of the hypotheses that have been, or might be, advanced respecting it, and the facts we possess that throw light on its causes and mechanism.

The Committee had proceeded but a short way in their experimental inquiries, when they found the conclusion forced on them, that the majority of the hypotheses (above enumerated) regarding the second sound, were wholly untenable. In some of their first experiments they found that the second sound might be absent, although the first sound was present and the systolic and diastolic actions were quite normal. The second sound, for example, was suppressed by—1, pressure on the roots of the arteries; 2, by hooking up a valve of each set of sigmoids; 3, by suspending the heart out of the chest; 4, by inverting the arteries, &c. (see Expt. *passim*): the first sound and alternate ventricular actions continuing unaffected in any material degree in each case. Such facts, of which there are many in the accounts of the experiments, seemed to the Committee quite incompatible with any other hypothesis respecting the second sound than the

* In the four experiments just referred to, the instrument was applied to the arteries near their roots.

last, viz. that which refers it to the action of the semilunar valves. Besides, several of those hypotheses appeared liable to the weighty preliminary objection, that they are wholly arbitrary, and without any foundation, so far as the Committee have been able to ascertain, in accurate observations or experiments. Under those impressions the Committee think it best to proceed at once to state the facts which, in their opinion, tend to establish the action of the sigmoid valves to be the cause of the normal second sound. For this some repetition perhaps may be necessary, but will, it is hoped, be excused.

The following experiments were made with especial reference to the mechanism of the second sound.

1. Pressure with the fingers and thumb was exerted on the arteries close to the sigmoid valves, so as to flatten the tubes a little, and the second sound, previously clear, and in every respect normal, was immediately suppressed, and a bellows murmur was heard instead: this murmur ceased, and the normal sound returned instantly on the removal of the fingers. (Expts. 7 and 10).

2. A degree of pressure sufficient, it was conceived, to change but very slightly, if at all, the shape of the vessels, gave to the finger sensations of currents moving in opposite directions,—the one current, from the heart, more striking and coinciding with the systole,—the other, towards the heart, less forcible, and synchronous with the diastole, and ending suddenly by a sensation of flapping or jerking. (Exp. 14).

3. The fingers being applied gently to the regions of the sigmoid valves, and the ear-tube applied to the heart, the flapping sound was heard, and a sensation as of a gentle tap was felt by the finger in coincidence with the diastole and second sound. (Exps. 10 and 14).

4. One valve of each set of sigmoids was hooked up in each artery successively, and the jerking motion invariably ceased, with one *apparent* exception only, and continued suppressed in the artery in which a valve had been so hooked up. If a valve in one artery only was so engaged, the second sound was weakened; but if a valve of each set of sigmoids was fixed, then the second sound wholly disappeared. In some instances there was a murmur of the sucking or blowing kind following

the systole during the suspension of the valve; in other instances there was absence of sound simply. (Exps. 4, 6, 12, 13).

5. The arteries were cut across close to the sigmoid valves, the veins being left entire, and the heart beating with considerable force; the ear-tube was then applied, but gave only one sound, and that one coincident with the systole. (Exp. 14).

6. In the separated heart the first sound was repeatedly observed, but the second sound never.

Summary and Conclusions.

1. The first sound of the heart, as heard in the chest, is generally complex in its nature, consisting of one constant or essential sound, and one perceptible only under certain circumstances. This constant element of the first sound may be considered as intrinsic, appearing to depend on the sudden transition of the ventricles from a state of flaccidity in diastole to one of extreme tension in systole; while the extrinsic, or subsidiary sound, which in a variety of circumstances contributes largely to the first sound, arises from the impulse of the heart against the parietes chiefly of the thorax.

2. The collisions of the particles of the blood amongst each other, or against the interior parietes, valves, &c. of the heart, do not appear to have any share in the normal first sound of the heart; neither do the motions of the auriculo-ventricular valves; and the attrition of the opposite interior surfaces of the heart's cavities seems purely hypothetical.

3. The principal and apparently only cause of the second normal sound of the heart is the sudden closure of the sigmoid valves, by the columns of blood that recoil back on them during the diastole, impelled by the elastic contraction of the arteries.

4. The columnæ carneæ appear to act simultaneously with the parietes of the ventricles, and in such a manner as to make it apparently impossible that the auriculo-ventricular valves should close with a flap in the same manner as the sigmoid valves*.

* An opinion which is further confirmed by the anatomy of the heart of the domestic cock, in which M. Boullaud (Du Cœur, tom. 1.) appears to have heard both sounds with the naked ear. If that animal there is no tricuspid valve resembling that of man, but the valvular office is discharged by laminar ex-

To conclude : the Committee feel strongly that the subject of the heart's motions and sounds requires further investigation, especially in their pathological relations, and a wider range, and greater variety of experiments, than have hitherto been performed.

NERVES AND MUSCLES OF THE ORBIT.

To the Editor of the Medical Gazette.

SIR,

I COULD not help regarding Mr. Thurnam's communication, on the comparative anatomy of the muscles and nerves of the eye-ball, as one of considerable interest. The spirit of research, as well as the correct feeling it displays, appear to me worthy of commendation ; and I think the question put by that gentleman is capable of a satisfactory answer.

The notion that the retractor muscle of the eye of quadrupeds is intended simply for the suspension of that organ, cannot now, I think, be maintained. The fact that this muscle is found only in those creatures who possess the *haw*,—that it neither exists in the quadrumana, or in man,—and that in birds there is a direct communication between the third eye-lid and the quadratus and pyramidalis muscles, which are absent in quadrupeds, all seem to imply that there is a relation between the two. This is now, I presume, very generally admitted.

In experiments on the eyes of quadrupeds, I have always found that on pushing the ball backwards and from

the temporal side, the haw has been made to start forward over the front of the eye. The question that I would offer for consideration, then, is this—does the action of the retractor muscle, conjointly with that of the abductor, pull the eye backwards and outwards in a similar manner to that in the experiment above noticed, and thus cause a protrusion of the haw ? If so, we see at once, why these two muscles should be so intimately connected as they are made to be, by being supplied with branches of the same nerve. Undoubtedly, the arrangement of the nerves of the eye generally would lead to the conclusion, that where there is a common distinction of nervous filaments, there must likewise be a relation, more or less, between the offices of the different parts to which they go. We see this principle displayed here in the most striking manner ; as, for example, in the case of the levator palpebræ and levator oculi, so that we cannot but regard it as one of first-rate importance. Sir C. Bell seems to have entertained some idea of there being a relation between the action of the two muscles in question, — “ that there is something common to the retractor oculi and the rectus externus*.” Elsewhere, however, Sir C. Bell says,—“ In quadrupeds I have ascertained that the oblique muscles act when the haw is protruded, but I have also found that the retractor oculi alone is capable of forcing forward the haw†.”

On the whole, I see no reason for concluding that the fact of the retractor muscle being supplied by the sixth nerve, at all militates against the explanation of the functions of the muscles and nerves of the eye-ball, as given in my paper of the 24th September. As Mr. Thurnam has himself remarked, the view suggested by Mr. Hunt, and since carried out and perfected by himself, refers to the *primary* and more important functions—functions which are common to all creatures in which the eye is fully developed ; whereas, the fact of the branches of the sixth nerve supplying the retractor muscle has reference to secondary arrangements, and such as are but partial in their application.—I have the honor to be, sir,

Your very obedient servant,

JOHN WALKER.

Manchester, Nov. 28, 1836.

tensions of the substance of the parietes of the ventricle, which meet in the middle, so as during the systole to cover the auriculo-ventricular orifice.

TREATMENT OF LUNG DISEASE.

To the Editor of the Medical Gazette.

SIR,

If it be not a generally-known fact that the tartar emetic is such an excellent remedy for inflammation of the mucous membrane of the lungs, I take the liberty of sending you the following case, in addition to that of Dr. Kemp, which, if you consider worthy a place in a corner of your valuable journal, is quite at your disposal.

A short time since I was suddenly called to a Mrs. B., æt. 28, married, but without children, of consumptive aspect, and whose father died of phthisis. She had been suffering from an affection of the lungs previously to this, for which she had had the advice of a medical man, and was much better, some days before I saw her. When I saw her she was labouring under the greatest degree of dyspnoea it has ever been my lot to witness; a most distressing cough, so that she could not speak; and a pulse of 130. My impression at the time certainly was, that she could not live: however, I determined to try the effect of tartarized antimony, and ordered the following:—

Antim. Tart. gr. ij.; Træ Digit. ℥xxx.;
Oxym. Simp. 3vj.; Aq. Distil. 3vij.
Cap. coch. ampl. ii. quaq. h.; and
a blister to the chest.

This treatment, sir, acted like a charm, and in two or three days I had the satisfaction of seeing my patient in a comfortable condition (comparatively.) I was soon after obliged to discontinue the medicine, as it occasioned so much sickness. The after-treatment was such as would suggest itself to every enlightened mind.

I should say though, that after the violence of the attack had subsided, my patient laboured under the most marked symptoms of tubercular disease, and I scarcely dared to hope she would be restored to health; but they gradually gave way, and in six weeks she was as well as she had been for the last two years.

In the latter part of my treatment I gave her the træ. ferri mur. in ℥x. doses, and think it did some good; but I certainly cannot lay claim to much credit for any thing I did towards the

removal of the phthical symptoms, and am disposed to think that nature effected the cure.—I am, sir,

Very respectfully yours,

EDWIN ELLIS.

Tulse Hill, Brixton,
Nov. 30, 1886.

DR. EDWIN HARRISON ON PHYSICAL SIGNS.

[Dr. EDWIN HARRISON, in continuation of the investigations connected with the physical signs of disease, in which he has been for a considerable time engaged, and some account of which has been communicated to our readers by his friends Dr. Williams* and Dr. Clendinning†, has transmitted to us the following propositions.—ED. GAZ.]

One or more of the following circumstances present themselves in a sufficient number of instances to deserve, I think, the attention of those who take an interest in physical signs:—

1. A depression about the height of the lower dorsal, or first lumbar vertebra, from which the finger, in mounting along the spine, will come to another depression, corresponding with tolerable accuracy to the height of the diaphragm at that part.

2. On moving the hand along either side of the chest vertically, on what may be considered as the median line, it will sink into a depression corresponding to the height of the diaphragm on that side.

3. A depression, or depressions, between the ribs, can be felt, or seen, or both felt and seen, at each abdominal inspiration, indicating (at least in the physiological state) the presence of the diaphragm in that part of the chest.

By this means the height of the diaphragm on the left side can be judged of, to a certain extent, even through the heart.

Query—What relation do these last-named depressions bear to the tilting up of the chest, which occurs not merely at its lower parts, but as high up at least as the lateral depressions previously mentioned?

* MED. GAZ October 3, 1885.

† Ibid. July 23, 1886.

It is scarcely necessary to add, that these remarks are offered as mere generalities, and, as such, are open to exceptions, limitations, &c. some of which I hope to be able to speak of hereafter with more precision than I can at present.

If it should turn out that my opinions are not so original as I believe them to be, I trust that I shall always be found ready to make the avowal.

ANALYSES AND NOTICES OF BOOKS.

“L'Auteur se tue à allonger ce que le lecteur se tue à abrégé.”—D'ALEMBERT.

Elements of the Practice of Physic; presenting a View of the present state of special Pathology and Therapeutics. By DAVID CRAIGIE, M. D. F.R.S.E., &c. &c. Edinburgh, 1836.

THERE exists not, in medical literature, a greater desideratum than a good elementary work on the practice of physic. The voluminous “Study” of Mason Good, and the elaborate essays in the “Cyclopædia,” and in the “Dictionary” of Dr. Copland, form great stores, from which the student may draw, when seeking for all that is known on any particular subject; but they are scarcely adapted for the student, who requires to have his knowledge in a more condensed form, and, as it were, already digested for him. We never expect to meet with any work which shall equal the “First Lines” of Cullen; so admirably suited to its purpose, that it kept possession of the schools long after the theory which pervaded it had become obsolete. Long was it attempted, by notes and additions of various kinds, to accommodate it to the progress of science, but the effort has become utterly hopeless, and the work may now be regarded as the production of a by-gone period, no longer qualified to constitute the hand-book which is to initiate the student into the mysteries of physic. Such has been the dearth of efficient successors to Cullen in this department, that we apprehend lecturers on medicine must often be at a loss what elementary work to recommend to their pupils: for there are several which profess to have supplied the deficiency, yet they are all either superficial and defective, or

marred by some peculiar crotchets of the author's own, to the exclusion of sounder doctrines; and thus they become unsuited for their ostensible purpose.

The work before us seems to be calculated to hold an intermediate place between the more superficial books manufactured professedly for students, and the elaborate volumes above alluded to. The first volume only has appeared, and it seems intended that there shall be but two altogether. This would make about 2000 pages of a pretty close type, and therefore affords ample space for the intended purpose. It is quite folly, or affectation, in any man to suppose that he can construct a system calculated to convey any thing like a complete view of the present state of medical science, from his own individual observation and experience. Dr. Craigie has wisely avoided attempting this, and has endeavoured, in its place, to present us with a work embodying the “united result of the observations and researches of all the ablest pathologists and physicians by whom the science of medicine has been cultivated, and by whom it has been simplified, improved, and rendered energetic.”

Each chapter is preceded by a list, chronologically arranged, of those works upon the subject to which it relates, which Dr. Craigie deems most worthy of being consulted, and a condensed view is given of the leading doctrines and facts, followed by the inferences of the author himself. Established modes of treatment, whether old or of recent introduction, are throughout preferred to those which, if possessed of more novelty, are still under probation, and the pathological characters of the disease are always referred to in connexion with the therapeutic indications.

Of the fulness of the articles some idea may be formed from this—that the chapter on Ague occupies 114 pages; within which space is comprised a longer or shorter notice, we really believe, of every important point connected with the history of the disease, as well as of numerous remedies which have at various times been recommended.

Upon the whole, we are inclined to regard Dr. Craigie's *Elements* as the best we at present possess; and we trust that the second volume will not be delayed in the manner which has of

late become the *fashion*, rendering so many of those works which are brought out in parts comparatively useless.

Coup D'Œil sur Les Hopitaux de Londres, et sur l'état actuel de la Médecine et de la Chirurgie en Angleterre. Par EDWIN LEE, Membre du Collège Royal des Chirurgiens, Londres.

It can scarcely be expected that the work bearing the above title should afford much information to the English reader, nor is this the author's object. Mr. Lee has visited the principal medical institutions of the Continent, and has thus had an opportunity of observing the general ignorance which prevails with respect to the state of the hospitals in this country; and with a view of contributing to remove this, has given a short sketch of the metropolitan institutions of England, which he has very properly written in the French language, and published abroad.

It is, we believe, the only effort to enlighten our neighbours on the subject which has been made since the work of M. Roux; which has been rendered obsolete by the numerous changes that have subsequently occurred.

NEW GERMAN PUBLICATIONS*.

Denkwürdigkeiten in der ärzlichen Praxis. (Memoirs and Papers relating to Practical Medicine.) Von DR. J. H. KOPP. Drei Bände. Frankfurt, a. M. 1836.

THE name of Dr. Kopp, of Hanau, is somewhat familiar to our readers, through his able article on thymic asthma, which we lately published. That article is contained in the third volume of this collection, along with a variety of other contributions to medical practice. The second volume is wholly devoted to an estimate of the homœopathic quackery.

Die Erkenntniss und Heilung der Ohrenkrankheiten. (On the Nature and Treatment of Diseases of the Ear.) Von DR. WILHELM KRAMER. Berlin, 1836.

Sammlung auserlesener Abhandlungen und Beobachtungen aus dem Gebiete der Ohrenheilkunde. (A Selection

of Papers on the Treatment of Ear Diseases.) Herausg. Von DR. C. G. LINCKE. 1—3. Leipzig, 1836.

The first of these works is a systematic treatise, in which the diseases of the ear, and their appropriate remedies, are regularly noticed. The second is a production which appears periodically (not, however, at regular intervals), on the same subject: among the selected papers are some by the first names in Germany.

Versuch einer pragmatischen Geschichte der Anatomie und Physiologie, vom Jahr 1800—1825. (Historical Account of Anatomy and Physiology.) Von DR. BURKARD EBLE. Wien, 1836.

A work of great research; containing a mass of information relative to the strides which anatomy, general and particular, human and comparative, has made during the first quarter of the present century. The bibliography alone would render the volume one of great value to anatomical teachers.

Das Blut in mehrfacher Beziehung physiologisch und pathologisch untersucht. (Physiological and Pathological Investigations concerning the Blood.) Von DR. HERMANN NASSE. Bonn, 1836.

Untersuchungen zur Physiologie und Pathologie. (Physiological and Pathological Researches.) Von DR. F. NASSE und DR. H. NASSE. Hefte 1—3. Bonn, 1836.

The volume on the Blood is an elaborate treatise, full of the fruits of experimental inquiry. The other work, by father and son, is on miscellaneous subjects, appearing in successive fasciculi.

Sammlung auserlesener Abhandlungen über Kinder Krankheiten. (Select Essays on the Diseases of Children.) Von F. J. v. MEZLER. Bände 1—5. Prag. 1833-6.

A very superior work to the *Analekten*, lately noticed.

Paris und die Rheingegenden. Tagebuch einer Reise im Jahre 1835. (Paris and the Rhine country; being Notes of a Tour, &c.) Von DR. C. G. CARUS. Zwei Bände. Leipzig, 1836.

We have here a very interesting ac-

* Imported by Mr. Schloss, of Great Russell-street, Bloomsbury.

count of a tour by the celebrated Carus, the comparative anatomist. His notes of his visit to Paris, where he had every advantage of mixing with all the *savans*, and of seeing every thing worthy of being seen, are, as might be expected, shrewd, intelligent, and valuable. We wish the distinguished author had crossed the Channel, and reported progress respecting medical affairs in this country: his observations, we doubt not, would have created a sensation in the professional world similar to what Von Raumer's have in society generally: no disparagement, however, to M. Carus, in comparing him with the Berlin professor of history, whom we do not estimate at any high rate.

De Retina Observationes Anatomico-pathologicae. (Anat. Phys. Observations on the Retina.) Auctore B. C. R. LANGENBECK, M.D. Göttingæ, 1836.

An elaborate quarto, containing a very complete account of the structure and functions of the retina. It is illustrated with plates representing various objects of comparative anatomy.

Das System der Circulation in seiner Entwicklung durch die Thierreihe und im Menschen. (The Circulation in Animals and in Man.) Von Dr. C. H. SCHULTZ. Stuttgart und Tübingen, 1836.

Supplemente zur Lehre vom Kreislaufe. (Additions to the Doctrine of the Circulation.) Von Dr. A. F. MAYER. Hefte 1 und 2. Bonn, 1827-1836.

Further contributions on the subject of the circulation. The first is a systematic work. The others contain some further elucidations of Professor Mayer's views.

Einleitung in die technische Chemie für Jedermann. (Introduction to Practical and Popular Chemistry.) Von Dr. F. F. RUNGE, Professor an der Universität zu Breslau. Berlin, 1836.

Well calculated to fix the students' attention; it abounds with coloured representations of the various substances, as they are met with either in their native state, in solution, or as precipitates. The idea of presenting these to the eye by means of slips of coloured cloth pasted on the page, has, we believe, been

borrowed from Dr. Thomson of Glasgow.

Handwörterbuch der praktischen Arzneimittellehre. (Dictionary of Practical Materia Medica.) Von Dr. L. W. SACHS und Dr. F. P. DULK. Theil. 1--3. Königsberg.

This promises to be a very useful work of reference: the third and last volume is not yet completed.

MEDICAL GAZETTE.

Saturday, December 10, 1836.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tuere; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

PARENT-DUCHATELET ON PROSTITUTION.

THIS extraordinary work is full of interest, both for the medical and general public: its details are of a nature calculated to explode many errors, as well as to establish many valuable facts. We shall endeavour to give something like a summary view of it to the reader, who may not have leisure to peruse it for himself.

What is to be done with prostitution in a state? This is a question which has often puzzled legislators. To suppress it as an evil may have been a well-intentioned project in the infancy of society; but the time has long gone by since the possibility of such a scheme was dreamt of. Under the most ancient governments, public women were permitted; and, in Rome, all such persons were obliged, on pain of banishment, to have themselves registered by the ediles. Modern Rome has long followed the example of its venerable mother, and the system of inscription has been practised there with much regularity from an early date. Even in this country, when Rome had so much influence over our religion and

morals, licenses used to be granted systematically to the keepers of brothels, and the higher ecclesiastics derived no inconsiderable portion of their revenues from that polluted source. At present it is well known how lax are our regulations in this respect—no cognizance whatever being taken of those who pursue prostitution as a trade, unless they happen to attract attention by some infraction of social order; while our French neighbours possess the most regular system in the world respecting these matters, and, in fact, have become the envy and the model of several European states. Which policy is the better, the relaxed or the strict—that which prevails amongst us, or that amongst the French—may be made a question: but we believe there can be little doubt that, with all their strictness and discipline, there is far more libertinism and profligacy in the French metropolis than in the British.

Startling assertions have been sometimes made relative to the prodigious number of prostitutes in London: it is not long since a demi-official report in the newspapers stated *forty thousand* to be somewhat about the mark. But a hint or two from Parent-Duchatelet will show us the vagueness which usually attends those round-number calculations. In Paris itself, it appears that until recently it has been the common practice to make similar exaggerations. Twenty, thirty, nay *sixty thousand*, has been stated as about the number of *filles publiques* in that metropolis. Writers in the political journals, whether for or against the administration, assumed *ad libitum* whatever estimate seemed to them most probable, or perhaps suitable to their purpose; and even persons who, from their connexion with the government, had means of access to more exact information, have commonly talked of *eighteen* or

twenty thousand. Now what thinks the reader is the actual number? Duchatelet states it precisely. He transcribed into his volumes the entries in the registries of the police, made regularly month by month for twenty-one years (from 1812 to 1832), and not until the year 1829 does the number of prostitutes in Paris reach 3000; and the greatest number is that entered in 1832, namely, 3617! So much for the value of approximations—such as we very much suspect those to be, which assert that there are twenty, thirty, or forty thousand public women in London. Figures, like facts, are stubborn things.

The system of registering prostitutes can scarcely be said to be of long standing in France: it is only, indeed, of late years that it has been practised in such a manner as to attract general approbation. The first suggestion relative to inscribing the *names* in the police registers was made not earlier than 1765, and it was some years later (1771) that an individual presented a memorial to government, on the propriety of taking cognizance of the *health* of those inscribed. The commission which was charged with the consideration of this project, reported—"that the suggestion regarding a *surveillance sanitaire* was the dream of a benevolent man, but that it was wholly impracticable."

A mode of registering of some sort was adopted previous to the revolution, but it was clogged with gross abuses. The women were inscribed, and taxed, and visited; but the official people—nay, the medical men—whose duty it was to make the requisite inspections, derived a vile pecuniary profit from the opportunities which their situation afforded them.

Since 1804 the administration of police has taken under its own charge both the sanitary visits and the inscriptions; and much order and regularity

have prevailed in consequence. Registers kept with extreme care, now exhibit at one view both the numbers and state of health of the women inscribed. Nor is this all: in 1828 another important arrangement was made: the certificate of birth has been rendered necessary,—so that the exact age of every female on the books is known. This latter regulation is attended with much advantage; for very few of the applicants being provided with their *actes de naissance*, a communication with the local authorities is requisite, whereby overtures are occasionally made for restoring some of the unfortunate females to their friends.

It may probably be said that there are more prostitutes in Paris than those on the books of the police. That we shall not gainsay; but the number cannot be very considerable. The police have their eye on all whom they suspect as *insoumises*, and the moment they catch them in any overt proceeding connected with prostitution, they put them immediately under arrest, and enter them in the registers as a matter of course.

On the causes leading to this degraded condition of life the author makes several sound reflections. He notices all the more ordinary inducements that operate on weak minds—the love of variety, of finery, of *gourmandise*, &c.; he comments on the neglect of education—the selfishness and cruelty of parents among the lower ranks of society: but he goes deeper towards the root of the evil—he points to the deplorable disarrangement which prevails in society, whereby females are left a prey to idleness—most of those occupations which would suit them being engrossed by men. “Is it not disgusting,” says Parent-Duchatelet, “to see, in our shops and coffee-houses, so many *men* in the vigour of their age leading such effemi-

nate lives, with scarcely any other employment than that of wiping vessels, or handling rags?” Rousseau long since pointed out this anomaly, and some of our ablest English writers have also denounced it. Fashion, however, which is omnipotent in these matters, must have its way; and *men-milliners* must be forthcoming, at whatever cost.

Some most singular facts are mentioned with regard to the motives which occasionally lead to prostitution. Any other authority would be scarcely credible; but full credit cannot but be accorded to Duchatelet,—martyr as he proved himself in the cause of truth. He assures us of several instances having come to his knowledge of women being led to prostitution through a *virtuous* or moral motive, urged, however, by distress. “Il n’est pas rare,” says he, “de voir des femmes mariées, abandonnées ou privées de leur mari, et par conséquent de tout soutien, devenir prostituées dans l’unique dessein de ne pas laisser mourir de faim une famille nombreuse; il est plus commun encore de trouver de jeunes filles, qui ne pouvant trouver dans le travail les moyens de pourvoir aux besoins de leur parens vieux et infirmes, font le soir le métier de prostituées, pour compléter ce qui leur manque; j’ai trouvé trop souvent des notes particulières sur ces deux classes de prostituées, pour n’être pas convaincu qu’elle est à Paris plus nombreuse qu’on ne pourrait le croire.”

These persons belong to that class called *filles isolées*, and could never endure the sort of life which is led by those belonging to the *maisons publiques*. Of the manners and habits of the latter class, as well as of the *dames de maison*, and of all those employed about them, we have such a picture as could not well be imagined, without being surveyed. Only fancy a separate

world of people, with an aristocracy, a middle class, and a populace: the people, too, governed by rulers whose authority knows no bounds—who, in the pursuit of a traffic a hundred times worse than the slave-trade, reduce their unhappy subjects to the most degrading occupations, to a condition comparable only with that of brutes, did not the hideous immorality accompanying it render such a comparison but too flattering. Such is the tyranny of those (so called) *dames de maison*.

Under the sway of these despots, the lives led by their victims is, as may be imagined, wretched beyond description. Obligated to prowling about the streets, or wander in the fields for hours, exposed to all kinds of weather, they are thrust, towards the end of the night, into some miserable corner, where the only resource for many of them is to forget their wretchedness in the most disgusting intoxication.

What, it may be asked, is the end of all this? What becomes of those unfortunates in their latter days? The common opinion is, that once they have plunged into their headlong career, retreat is impossible—that they soon reach the bottom of the abyss: that they all die in the hospitals, eaten up with disease. This, however—and there is some relief in the knowledge of the fact—happens to be a mistake. Prostitution, to use the language of Duchatelet, is but an *episode* in the life of the majority of those women; they, in general, only pursue the trade for a certain number of years, after which they contrive to live as other people do. Some return to their parents or relatives; others form connexions with old *célibataires*—sometimes with artisans of the lowest classes. A great many of them obtain situations as servants; some marry, occasionally even with men of rank; others, in fine, but they are comparatively few, retire with a competency,

which they have saved up by strict economy—a thing which certainly can never happen to those under the direction of the *dames de maison*.

Here we shall close this summary sketch. We have only touched on some of the more general topics treated in the volumes: we have said nothing of the punishments, the prisons, the houses of correction and refuge, nor of the valuable suggestions offered by the author on these and a multitude of other points. When next we notice the work, as we hope to do ere long, we shall be more strictly professional; for there are a number of interesting subjects scattered through the volumes in connexion with the statistics of disease, with which we should like to make our readers acquainted.

WAKLEY AND HIS "ACT."

THE Lancet of last week presented a laughable exhibition—Wakley's attempt to write fine and be genteel! It reminded us for all the world of Jack Falstaff's determination, in future to "purge and live cleanly," as a gentleman ought to do.

But the explanation of the phenomenon is easy. Wakley is desperately sore about that unfortunate bantling of his: he sees all its faults well enough; yet, fathered as he is with it, what can he do but endeavour to back it up?

In his quandary he sends a parcel of *fishing* letters to his correspondents—those especially that he can depend upon—just to ask them "How does my Act work?" Of course they answer by return of post that it works *beautifully*. Any one that was not blinded by a parent's foolish fondness, would see, however, that among the replies he received, and which he publishes as an answer to us, there was scarcely one which offered even the shadow of a fact. We said there were many medical men

who had been unable to obtain their fees under the Act; and we believe so still.

No fishing letters have been written by us to our correspondents: yet we have got facts as many as we want. "Chirurgus" was a difficult nut for Mr. Wakley to crack: yet perhaps the gentleman whom we have now the honour to introduce to him will not prove a less stubborn witness against the mischiefs of his bungling legislation. We shall not blunt the force of our correspondent's letter by any comment of our own—at least for the present.

To the Editor of the Medical Gazette.

SIR,

THE following facts, I think, will shew the total inefficacy of the act for remunerating medical witnesses, and that where it ought, if possible, to have worked well, a medical man being the coroner.

I was sent for to see a person, who when I arrived was dead. I found, upon inquiry, that she had miscarried the previous day. A half-pint bottle, in which there had been turpentine, was in the room. From this and other circumstances I thought it was a case in which some legal steps ought to be taken to inquire as to the cause of death. Upon acquainting the magistrates, they were of my opinion, and ordered the coroner (Mr. Ferrier, a surgeon) to hold an inquest. This gentleman accordingly requested a surgeon, a friend of his, to make a post-mortem examination of the body, and summoned me to attend the inquest, at which he held forth very learnedly, favoured the jury with a long harangue about the treatment of tape-worm by turpentine, and stated that a large dose of turpentine had the same effect upon the system as small and repeated doses had. After the inquest he refused to give me an order for payment, stating as his reason that I had not a *special summons*! I then appealed to the magistrates, who told me that they had no power to make him do it.

If Mr. Wakley really intends to amend the act, he had better insert a clause preventing medical men being

coroners, as it gives them an opportunity of forwarding the interest of their friends, and gratifying private pique in their public capacity, which in this case most decidedly has been done.

I am, sir,

Your obedient servant,

CHAS. C. ALDRED.

Yarmouth, Norfolk,
Dec. 3, 1836.

TRIBUTE TO SIR CHARLES BELL.

A VERY handsome, richly ornamented, silver urn has been presented to Sir Charles Bell by some (a hundred and thirty) of his professional brethren, on the occasion of his leaving London to take up his abode in the northern metropolis. We are requested to state, that any of the subscribers may view it at the makers, Messrs. Storr and Mortimer, Bond-street, where it will remain till the 20th instant.

LEGAL MEDICINE.

[WE have thought the following trial and inquest worth preserving: the first on a subject, not certainly of rare occurrence, but requiring the most careful attention on the part of medical witnesses; the second curious, and exemplifying the mischief that may arise from the use of unsound food. The poison was probably generated in the bacon, by a sort of decomposition similar to what has been sometimes observed to take place in German sausages.—ED. GAZ.]

INFANTICIDE — CONCEALMENT OF THE BIRTH.

At the Old Bailey, on Friday last week, Jane Hale, spinster, aged 18, was indicted for the wilful murder of her male infant child, by suffocation; and in another count in the indictment the prisoner was charged with inflicting certain wounds with a sharp instrument on the neck of the infant, by which its death was occasioned.

Mr. Bodkin stated the case to the jury.

Elizabeth Seymour deposed, that she was nurse in the family of a lady named Jeffrey, who resided at Stoke Newington. The prisoner was servant of all work in the same family, and had lived there for about six months prior to the present charge. In consequence of her altered appearance, witness had several times taxed her with being pregnant, but she denied it. On the morning of the 19th of November she complained of illness, and

rent up stairs to her bed-room. Witness informed Mrs. Jeffrey of the circumstance, and subsequently went to the prisoner's bed-room, and found her packing up her clothes, her mistress having given her warning to leave her service that day. Witness went to her bed-room again after some interval, and found the prisoner in the same position as before, and she then observed some stains upon the floor. She told the prisoner that her mistress had gone to fetch Mr. Drayton, the surgeon, when she replied that she did not want him.

Mrs. Sarah Jeffrey corroborated the chief part of this testimony.

Cross-examined.—The prisoner, while in her service, bore a good character for humanity and kindness of disposition.

Mr. G. B. Drayton, a surgeon, residing at Stoke Newington, proved that on the morning of the 19th of November last he was called upon to attend the prisoner, and found her in her room quite dressed, packing up some things in her box. She said she was preparing to go away, and that she was then quite well. After some conversation with her he proceeded to examine her, and found that she had lately been delivered of a child. She denied it; upon which witness said he was convinced of the fact, and if she did not tell him where the child was he should call the police. She hesitated a few minutes, and then said, "It is under the bed." Witness lifted up the bed-clothes, and found a bundle tied up in a woollen covering. On removing the wrapper, he found a second covering of linen; and having also removed that, he discovered the head and face of a child. On examining the neck he observed a cut, and asked the prisoner how she could have been guilty of such a disgraceful act. She made no reply. Witness then sent for the police, and they took possession of the child's body; upon examining which, they found it still warm, and the limbs flexible;—and, from the appearances which the body presented, it appeared to have been dead about half an hour. Witness then told the prisoner that she would save the police much trouble if she would point out the instrument with which she had inflicted the wound on the neck of the child. She then pointed to a knife, and witness observed some spots of blood upon the blade. On the following Monday, witness and Mr. Robinson, another surgeon, examined the body. The witness then proceeded at considerable length to describe the appearances it presented; and the substance of his evidence with regard to the cut on the throat was, that it would not have been sufficient

to cause death. The lungs were remarkably small, and of a purple colour, and from their appearance he was of opinion that the child had not breathed atmospheric air; but upon testing the lungs, by placing them in water, he found that they floated, and upon cutting them a slight oozing of air took place, which caused him to alter his opinion; and, from all the circumstances in the present case, he should say that the child was born alive, and that the marks of violence which he found, with the exception of the bruise on the head, were not sufficient to produce death. The contusion on the head might have taken place by a fall on the floor at the moment of birth. The wound on the throat was quite superficial. When an infant at its birth breathed freely, the lungs entirely filled out the cavity of the chest, and they were of a bright red colour, which was not the case in the present instance.

The case being closed for the prosecution,

Lord Denman said that the two great questions in the case were, first, as to whether the child was born alive; and secondly, if so, whether the prisoner had wilfully caused its death. He deemed it right, in this stage of the inquiry, to tell the jury that both questions appeared to be involved in so much doubt, that the bench were of opinion that the evidence was not sufficient to support the charge of murder; and unless the jury entertained a different opinion, and were desirous to hear a further discussion upon the points in question, it would be useless to proceed further as regarded the more serious offence. There could be no doubt, however, but that the prisoner had been guilty of concealing the birth of the child.

The jury intimated to his Lordship that in their opinion the charge of murder could not be sustained.

Mr. Carrington said, that he was much indebted to his Lordship for relieving him from a most anxious and painful duty—that of addressing the jury on behalf of the unfortunate prisoner, on a charge affecting her life, and he was willing at once to admit that the evidence had fully established the minor offence, that of *concealing the birth*.

A witness was then called, with whom the prisoner lived for three years, and who gave her an excellent character.

The jury, under his Lordship's direction, returned a verdict of *Not Guilty* of the murder, but *Guilty* of concealing the birth of the child.

The prisoner was then called up for judgment, and,

The Recorder proceeded to pass sentence upon her, observing that the learned persons who had tried the case had instructed him to inflict the fullest punishment the law attached to the offence of which she had been found guilty; and of the justice of the verdict every person who heard the case must be perfectly satisfied. As the organ and instrument of the Court, he was therefore called upon to sentence her to a confinement of two years, with hard labour, in the House of Correction; but the hard labour would not be added to the sentence until her state of health allowed it. It was needless for him to recal to her mind the suspicions and alarming facts disclosed upon the trial; but he must observe, that the circumstances which came out in evidence furnished at least probable grounds for believing that she had meditated, if not actually perpetrated, the murder of her helpless child.

POISONING WITH UNSOUND BACON.

AN inquest was held at Westminster Hospital on Monday last upon the body of Caroline Jones, who came by her death under the following circumstances:—Considerable interest was excited in consequence of a prevalent rumour that the deceased had been poisoned by some of the bacon which became impregnated with arsenic on the occasion of the late fire at Fenning's wharf, London-bridge.

Richard Jones, of No. 8, Franklin's-row, Lower Chelsea, messenger to His Majesty's commissioners of Tithe inquiry, deposed that the deceased was his daughter, and nearly 15 years of age. Her health had been always good from her infancy up to Sunday seven weeks ago. On the preceding evening, Saturday, 15th October, witness and his wife bought a piece of bacon at a shop opposite the Chelsea bun-house. The bacon was labelled 4d. per lb. It looked very good, and the shopman persuaded witness to buy 8½ lb. at a reduced price, warranting it to be good. It was cooked the next day, with greens. The whole family dined together, the deceased eating very heartily of the lean part of the bacon. During dinner, witness remarked a peculiar flavour in the bacon. It disagreed with him, and he ate very little of the fat, and none of the lean. Soon after dinner, he felt a burning sensation in his throat, and a disposition to vomit. About an hour after dinner, his son, who was afflicted with the St. Vitus's dance, was taken ill, and seized with pains and vomiting. The servant had gone out with a younger child, and returned about five o'clock, complaining of dreadful headache, and burning at her stomach. Wit-

ness gave her some tea, when she went to bed, and was attacked violently with spasms and retching, but nothing came off her stomach. Whilst witness was attending the deceased, another child, aged 8 years, was attacked in precisely a similar way. There were two other children, who had not partaken of the bacon, and they were not affected with any illness. Witness went to a druggist's shop, and procured calomel pills, of which he gave three grains to each of the sick children and their mother, and took five grains himself. The deceased continued ill for several days, and in a fortnight a medical gentleman was brought in, but as she grew worse, in the course of a week she was removed to the hospital, where she died on Friday last. Every one of the family who had tasted of the bacon was affected in the same way as the deceased, but not so seriously. Witness did not show the bacon to the doctor: he threw it down the water-closet. He had observed black spots upon it before he threw it away. Immediately upon finding the ill effects of it after dinner, he cut it open, and, besides the black spots, he particularly observed that it had a nauseous heavy smell, but very unlike that of putrid meat. He could liken the taste to nothing but that of sugar of lead.

Witness acknowledged that he was wrong in not calling in medical advice sooner, but he hoped that the purging produced by the calomel would have cured them all. He had heard of other families in Chelsea being made ill by eating bad bacon.

Mr. John Thomas, surgeon to the hospital (?), stated that the deceased was admitted on the 8th November, suffering very severe pains in the abdomen, and excessive purging. For about three weeks she seemed to be recovering; but after that she became worse, and died on Friday last. Upon the post-mortem examination, great ulceration of the stomach was observed, which was the immediate cause of death. The friends of the deceased had said nothing about the supposed cause of her illness until about three days before her death. The symptoms might have been produced by other causes than the taking of deleterious matter into the stomach; but witness was inclined to believe, from the evidence which he had heard given by the deceased's parents, that the bacon was the cause of the illness, and consequently of the death. Tainted or diseased meat would produce symptoms similar to those which the deceased exhibited. They might also have been produced by some mineral poison.

Mr. Keen, cheesemonger, of Grosvenor-

Row stated that the bacon, sold to Mr. Jones was bought of Messrs. Parry and Beazley, Holborn-hill, and he had never heard of any complaint about it until this day. The bacon had certainly not come from Fenning's wharf. He had sold all the better parts at 10d. and 11d per pound, and he was glad to dispose of the inferior parts at a low price.

John Brown, clerk to Messrs. Parry and Beazley, produced the invoice of the bacon sold by them to Mr. Keen. There was no part of the bacon diseased or tainted. It had not come from Fenning's wharf. He attributed the black spots spoken of by Jones to bruises.

The jury, after consulting for about twenty minutes, came to a unanimous verdict, that the "Death of the deceased was caused by eating unwholesome bacon, but that no blame was attached to the vendor."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Abstract of a Paper in the forthcoming Transactions, entitled "RESEARCHES on some Points of the PATHOLOGY of PULMONARY TUBERCLE. BY PETER NUGENT KINGSTON, M.D., Physician to the St. George's and St. James's Dispensary."

THE object of this paper is to shew, 1st, that the common pulmonary tubercle is a vascular texture; 2dly, that it sometimes originates in an alteration of the air-cells and their secretions; and 3dly, that now and then the disease is entirely healed, when it has even extended over a very large portion of the lungs.

I.—The opinion that pulmonary tubercles are destitute of nutrient vessels, and consequently of all the properties of organization, has prevailed since the time of Stark. The principal ground on which it rests is, that they cannot be injected from the vessels of the lungs. But here it is assumed that no vessels can be so minute, even in the most delicately organized parts, as not to admit and be brought into view by the fluids employed for anatomical injection, which is contrary to the opinions of many of our best anatomists and pathologists, and is irreconcilable with the fact, that the articular cartilages, when inflamed, exhibit red vessels, which, in the healthy state, are impermeable by injections.

The injection of pulmonary tubercles has not, however, been fairly tried, for the fluid has been thrown only into the pulmonary arteries and veins; whereas, those parts of the pulmonary structure which are impervious to air being nourished exclusively by the bronchial arteries and veins, it may be inferred that with these alone are the nutrient vessels of the tubercles connected, and that by the bronchial arteries alone can their injection be attempted with any reasonable hope of success.

The author then gives an analysis of seven cases of pulmonary tubercles possessing the ordinary appearance, and having during life given rise to the ordinary symptoms. On careful section, the interior, both of those which were yellow and opaque, and of those which were greyish and translucent, was distinctly seen to be traversed by red vessels, often of considerable length, making frequent ramifications and anastomoses, sometimes extending from the centre of the tubercle to its circumference, where they communicated with the vessels of the lungs.

If the vascularity of the common pulmonary tubercle be admitted, there is no longer any difficulty in explaining the changes of colour and consistence which take place in its interior during the several stages of its progress, and the frequent commencement of these changes in the centre; whereas, under the supposition that it is destitute of organization, these phenomena are inexplicable, or at least have received no explanation generally satisfactory to the profession.

II.—It was held by certain authors, nearly a century ago, that pulmonary tubercles sometimes consist of air-cells distended with morbid secretion, which has gradually solidified and acquired the various appearances presented by tubercles in their several forms and stages. During the last twenty years, observations in support of this opinion have been brought forward, first by Magendie and Cruveilhier, and since by Andral and Dr. Carswell. But the evidence is still considered by many as incomplete, and as needing addition and support from further investigations.

Dr. Kingston then relates cases in which the following series of appearances were observed in portions of the same lung.

1. Excavations at the apices of the lobes.

2. Bodies having the ordinary characters of miliary, crude, and softened tubercles.

3. Bodies which, to the eye and touch, scarcely differed from the preceding, but upon close examination were found to be

* Both cases slightly condensed from the *Times* report.

membranes filled with viscid mucus, to be continuous with the bronchi, and hence to be portions of the air-passages.

4. Bodies forming a transition between the third and fourth groups.

There appears no room for doubt that these were but different stages of the same disease; and hence it may be inferred that the tubercles originated in a thickening and distension of the air-cells; that the parietes of the latter continued to thicken, and their contents gradually solidified, till at last a total obliteration of their cavity was effected, and there resulted a number of solid, white or grey, more or less opaque bodies, frequently of rounded form, such as have received the appellations of miliary tubercles and miliary granulations.

This conclusion throws light upon several practical questions; in particular, it confirms the opinion of those who, while they allow the necessity of a predisposition, think that a lingering inflammation, or long-continued irritation of the air-cells, and minute bronchi, excite the disease in many who, though the diathesis existed, would otherwise have escaped.

III. — A few cases have lately been brought forward by Laennec and Andral to shew that, where a very small number of pulmonary tubercles exist, they are occasionally healed.

Dr. Kingston relates a case in which a tuberculous affection had been entirely healed, after having disorganized the whole of one lung, and a fourth part of the other. One lung consisted of little more than a congeries of excavations, all lined with healthy membrane, free from tuberculous and purulent matter, and inclosed by a thin lamina of condensed pulmonary structure. A fourth part of the other was taken up with hard carbonaceous masses, some of which were encysted, and a few contained in the centre a little yellow, opaque, dry, friable tuberculous matter. In each lung there were besides a very few encysted, withered tubercles, sufficiently indicating the nature of the lesion which had produced the excavations. The man first came into St. George's Hospital for a severe wound on the leg, from the kick of a horse. Of this he was perfectly cured in about four months. He came in a second time with inflammation of both kidneys, from getting wet. By this, and a supervening affection of the head, he was carried off in twelve days. During the periods of his stay in the hospital, an occasional fit of coughing, with expectoration, occurred in foggy weather, but there were no habitual chest complaints of any kind.

The healing of a tuberculous affection of

the lungs, so extensive as this, has no parallel on record, and had not, even by Laennec, been contemplated as possible.

OBSERVATIONS

ON THE

NATURE AND TREATMENT OF GANGLION.

By MR. ASTON KEY.

THE power which tendons have of forming bursal cysts, when they are exposed to extraordinary pressure or friction, is one among the many resources possessed by organized structures, to prevent the occurrence, as well as the consequences, of inflammation. It would seem that ganglia are not merely diseased bursæ mucosæ; for the former are found in parts where, in a state of health, bursæ do not exist. I look upon them as new structures, formed upon tendons, as pressure or friction, or undue exercise of a part, may call them forth. On the patella the presence of a bursa is accidental: it is not always met with in dissection; and probably its formation may depend on the exertion which the ligamentum patellæ has to undergo, or on the pressure which it may have to sustain, in the frequent act of kneeling. The contents of a ganglionic tumor differ from those of a common bursa mucosa. The latter secretes a fluid like ordinary synovia, for the purpose of lubricating the tendon: the ganglion most usually contains a substance like the outer layers of the crystalline lens, soft, viscid, and nearly solid. These crystalline ganglia, as they might not improperly be called, are frequently formed about the hand, especially on the extensor tendons, as they pass over the carpal bones; less frequently on the lower part of the theca containing the flexor tendons of the fingers, forming small but sensitive swellings near the metacarpus. They also are occasionally seen on the extensor tendons of the fingers where they pass over the joints, giving pain, and accompanied by a great sense of weakness in the part.

These crystalline ganglia are formed, as I have said, on the tendinous structure, and appear to consist of a double bag: the outer one tendinous and firm; the inner, like a synovial membrane, thin and secreting. In one that I examined on the tendon of the external gastrocnemius muscle, this double bag was distinctly seen. In most instances, the outer cyst cannot be separated from the inner; the whole seem-

g to be made up of one fibrous bag, creting on its inner surface.

The treatment usually adopted for those tuated on the back of the wrist-joint, is, burst the cyst by a sharp blow with a bok or any other hard body. If well med and sharply struck, it often effects the object of breaking it down; but it as equently fails, either from the firmness of the cyst or from the unskilfulness of the ow, or from want of sufficient resistance forced by the wrist. It is also a painful medy, and is occasionally productive of ore subsequent inconvenience than the anglion had occasioned. The more simple plan is, that of making a small puncture with the point of a lancet; or a cataract needle, when the tumor is small. There is no fear to be entertained of inflammation taking place; as the cyst is little disposed to inflame, and the closure of the opening, after the contents have escaped, by means of a band or piece of plaster, is a sufficient guard against its occurrence. I have never seen or known any mischief to arise from the operation of puncturing these ganglia; and their return equally prevented as by any other mode of treatment.

For the small tumors that occupy the base of the palmar side of the fingers, the puncture is the only remedy. Blisters or blows are ineffectual: the former are very slow in operating, and rarely succeed in removing them; and blows cannot be struck with sufficient accuracy to ensure a capture of the cyst. The cataract needle is the most convenient remedy: the tumor being sensitive, the patient experiences some pain in its introduction; but it is momentary, and the relief afforded is complete.

When the swelling is situated over the back of a joint on the extensor tendon, pressure should be kept up for some weeks after the evacuation of the cyst. A gentleman, who was much in the habit of writing, applied to me for a swelling of this kind on the first phalangeal joint of the right index: he complained of pain and weakness in the use of it, and was unable to employ the finger steadily in writing. A small puncture was made in it, and about a drachm of crystalline fluid escaped: a piece of ribband was bound over the joint, and firm pressure was thus made on the cyst. The fluid did not collect again; and by wearing the ribband for a few weeks, in order to secure and steady the finger when employed in writing, he regained the perfect use and strength of it.

I once punctured a similar swelling over the tendon of the trochlearis superior muscle of the eye; and it never shewed any disposition to return. Occasionally, the part that has been the seat of the ganglio-

nic enlargement becomes thickened after its contents have been allowed to escape; and a slight hardness remains, but does not interfere with the use of the part.

The ganglion patellæ is a cyst formed upon the expanded tendon that invests the surface of the patella. Its structure resembles that of the other ganglion, having a dense fibrous covering lined by a secreting membrane. The secretion differs from that of the crystalline ganglia, in being fluid; probably in consequence of having less albumen in its composition. I need not enter particularly into the ordinary modes of managing such ganglia, when they become large or painful. Blisters, stimulating plasters, and pressure with a bandage, are often resorted to with advantage. The more effectual plan for dispersing them altogether, is, to puncture them with a lancet, to let out the contained fluid, and to employ firm pressure with a bandage and plaster. If this does not prove permanently successful, the seton becomes the most ready, the most mild, and the most effective remedy that we have at command.

I have frequently had occasion to employ this remedy for this affection of the knee; and can aver it to be milder in its effects, and in the annoyance it causes the patient, than the common blister. If a few threads be passed through a ganglion patellæ of one knee, and a blister applied to another on the opposite limb, the patient invariably, I have noticed, complains of more suffering from the blistered surface than from the suppuration caused by the seton: and this is in accordance with what we know of the sensitiveness of the skin, compared with the sensibility of a bursa, even in a state of inflammation. The pain complained of during the stage of acute inflammation is inconsiderable; and the moving the threads, during the process of suppuration, occasions but little uneasiness. Sometimes a little feverish excitement is produced by the pus not escaping freely from the apertures, which, being retained, becomes decomposed: this inconvenience is remedied by keeping the openings, where the silk enters, free and clear. The seton should be kept in for several days after suppuration is established, in order to promote granulations, and to facilitate the escape of the pus. Even where the ganglion suppurates itself, the seton may be used with advantage, towards accomplishing these two objects.

The detail of cases in which the seton was employed is unnecessary, as they resemble each other in all points of practical import. The length of time required for the complete action of the silks, and the extent of the inflammation induced

by them, may vary in different individuals. Many cases have occurred in the hospital, during the last three years, in which the seton has been effectually employed; and, on the whole, I prefer it, as being more certainly effective, and combining with such efficiency the advantage of not being severe or painful.

It is not to the ordinary ganglion patellæ alone that its use is confined. The operation of the seton is more especially adapted to the indurated ganglion. By this kind of swelling, I mean one in which, from the continued existence of inflammation, the cyst of the tumor has become exceedingly thickened by successive deposits or layers of adhesive matter or fibrine, converting the tumor into an almost solid mass.

These hardened ganglia cause great uneasiness to the subject of them; and incapacitate the person from bearing on the part in kneeling, as well as weaken the limb in the act of extension. The appearance of these tumors, when they are laid open, sufficiently indicates their manner of growth, and also the mode in which the loose bodies, resembling melon-seeds, that are often found mixed with their fluid contents, are produced.

The operation usually employed for the cure of such indurated cysts on the patella and its ligament, is excision of the entire mass. The operation is easily performed, does not involve the joint in danger, and is effective in removing the disease. When the tumor is small, the operation is quickly performed; but if it be large, and overlap the synovial membrane, a surgeon cannot divest his mind of all risk of wounding the capsular ligament, especially if the base of the cyst be adherent to the subjacent fascia; and the operation requires some cautious dissection. Fortunately, the seton is equally successful in promoting suppuration of the cyst, as it is in the smaller and soft ganglia. But the most gratifying result is the entire disappearance of the hardened coats of the cyst by absorption. The indurated parietes appear to be produced, and to be kept up, by the irritation of the bag; which being filled up by the inflammation and suppuration established by the seton, ceases to act as a cause of irritation, and the absorbents set to work for the removal of the walls of the tumor.—*Guy's Hospital Reports*, No. 3.

ON THE EMPLOYMENT OF THE SUCKING PUMP IN STRANGULATED HERNIA.

M. KOEHLER, in 1821, effected the reduction of a scrotal hernia, by applying a

cupping-glass above it. Not having heard of the use of the pump in such cases, he did not attribute the effect produced to its true cause; but on seeing the paper of M. Busch, in *Hufeland's Journal* for 1832, he was induced to try this new method.

The first trial was upon a patient sixty years of age, who had laboured during nine years under scrotal hernia of the left side, which had become suddenly strangulated. He was affected with the most violent pains, and all the efforts of the surgeon to effect reduction proved abortive. Such was the state of matters on the 3d, when M. Koehler saw the patient for the first time. The hernial sac had now attained the size of an ostrich's egg; the countenance was shrunk, and expressive of great suffering; the skin covered with cold sweats; the abdomen tympanitic and hard; the pulse almost imperceptible; constipation of three days standing; hic-cough, and stercoraceous vomiting. One more, and that an ineffectual attempt, was made at effecting reduction by the taxis, when recourse was had to the exhausting pump. On the first application over the inguinal ring, borborygmus was heard within the hernial sac; and to the surprise of all, the reduction was straightway accomplished: the vomiting immediately ceased, and some hours afterwards the patient had an evacuation from the bowels. In the course of a few days the recovery was complete.

M. Koehler gives the details of six other cases of strangulated hernia, both inguinal and crural, in which the strangulation yielded to this means, after having resisted every other—an operation alone excepted. One of these, however, required considerable perseverance. A Jew mendicant, aged 62, had laboured under a scrotal hernia for twelve years, which had become strangulated in consequence of the mal-application of a bandage. When he came to the hospital the sac was as large as a child's head, and was tense, without being very sensible. He had vomited twice, and, notwithstanding the administration of clysters before his admission, he had been constipated during four days. The first application of the pump not having been attended with success, he was bled, and had large doses of calomel administered internally, while an anodyne ointment was applied to the part. No improvement being thereby effected, the pump was tried again; but it was not till its third application that some peristaltic movement became perceptible within the sac. The exhaustion was performed once more, when the reduction was immediately accomplished. The bowels acted soon after, and in a few days the patient was quite well.

of M. Koehler's colleagues have used the pump, in a case of strangum-bilical hernia, also with most happy result. A woman, fifty years and very corpulent, had an umbilical hernia of two years' standing, was partially irreducible: it became strangulated, with stercoraceous vomiting and constipation of three days' duration. The tumor was as large as an orange, hard, and very sensible. All remedies having failed, the air-pump was tried: its application gave pain, raised the integuments by the traction experienced; nevertheless the reduction was complete. In conclusion, this method succeeded happily in twenty-three very severe cases. *Koehler's Annalen.*

REDUCTION OF THE LEFT HEMISPHERE, WITHOUT AFFECTING THE INTELLECT.

M. BELL has communicated to the *de la Societe de Médecine* of Ghent, a case which presents considerable interest in relation to the functions of the brain. A young man of 16, habitually grave, taciturn, and of obtuse intellect, stated that he had been deceived by a woman, whom he was attached to, and determined, in consequence, to destroy himself. He discharged a pistol into his head, the ball from which penetrated by the aperture at the anterior part. About twenty cupsful of cerebral substance were evacuated by the opening, and a trocar was introduced to the depth of the wound, without meeting with the least impediment. The patient, who was at first insensible, recovered in twenty-four hours, presenting no trace of sensibility or power of motion or sight, however, was gone. The wound healed favourably: a considerable quantity of cerebral matter was lost each time the dressing, and at the end of twenty-seventh day the wound was completely healed—neither ball having been extracted. A remarkable change had taken place in the character of the youth. He became gay, intelligent, and talkative. Vision was never restored, but his sense of smell was quite unimpaired. Six months after the accident he was again subject to convulsions, which were relieved by one bleeding. At the end of two years he died. The great loss of substance which this individual had suffered had occasioned no derangement of the intellectual powers, notwithstanding that the balls had penetrated

very far back into the brain; and as the wound was situated at the middle of the os frontis, and beneath the left frontal protuberance—as besides, the course of the balls departed from the median line at an angle of about 15°—it is more than probable that the left lobe was destroyed.

COLLEGE OF SURGEONS.

LIST OF GENTLEMEN WHO RECEIVED DIPLOMAS IN NOVEMBER.

William Innes, Tain, Rosshire.
John B. Samuel, New Bridge-street, Vauxhall.
J. L. Eland, King's Cliff, Northampton.

NEW MEDICAL BOOKS.

The Fallacy of the Art of Physic, as taught in the Schools. By S. DICKSON, M.D., 8vo. 7s.

The Principles of Surgery. By JAMES SYME, F.R.S.E. Second edit. 8vo. 14s.

Cowan's Bed-side Manual, 18mo. 2s. 6d.

Lectures on the Morbid Anatomy of the Serous and Mucous Membranes. By T. HODGKIN, M.D. Vol. 1, 8vo. 10s. 6d.

Pathological Researches on Phthisis. By LOUIS. Translated by COWAN. 8vo. 12s.

UNIVERSITY OF DUBLIN.

LECTURES ON ANATOMY.

To the Editor of the Medical Gazette.

SIR,

ALLOW me to request that you will have inserted in the MEDICAL GAZETTE the annexed order of the Board of Trinity College, Dublin, for the purpose of counteracting any erroneous impression that might exist as to the delivery of the anatomical course in the University of this place.—I remain, sir,

Your very obedient servant,

FRANCIS BARKER,
Registrar to the Professors.

22, Bagot-street,
Dec. 1, 1836.

(COPY.)

Trinity College, Dublin,
Nov. 26, 1836.

Ordered by the Board, that the Professor of Anatomy and Surgery shall deliver five lectures a week in anatomy, at the hour of one o'clock, in their Anatomical Theatre, during the medical session, from the first Monday of November to the end of April in every year; and that this order be esteemed a "bye-law," agreeably to the 26th section of the 40th Geo. III.

By order of the Board,

(Signed) ROBT. PHIPPS,
Registrar.

NORTHERN DISPENSARY.

WE are glad to learn that, at a special general meeting of the Governors of this dispensary, held on Tuesday last, the following resolution was carried by a large majority; so that there is reason to hope the evils recently complained of will be corrected, and that the prosperity of the institution will ultimately be advanced.

Resolved—"That this meeting, in considering the causes which led to the resignation of the late medical officers of this charity, is bound to acknowledge that those gentlemen resorted to the most becoming expedient to vindicate their own honour, and to arouse the attention of the governors to the danger which threatened the existence of the institution.

"That this meeting has heard with regret, that the representations made to the Committee of the causes which led to their resignations, did not induce the Committee to adopt decisive measures for the protection of the charity; and this meeting considers it due to the medical officers making these representations, to thank them for their praiseworthy efforts to maintain the usefulness of the charity, and request that they will resume their several offices."

Increase of Burials, as compared with } 971
the preceding week

. The increase in this week's bill has arisen from several clerks of large parishes, who had neglected to make their reports in due order, having now made reports previous to the close of the year, for insertion in the General Bill.

Rain fallen, .575 of an inch.

NOTICES.

"S.," a Hahnemannite, who calls upon us "to confirm or refute" the statements of one Simon, had better tell us, in the first place, who the said Simon is: he may be a lineal descendant of Simon Magus for aught we know. Then we should wish to be informed who are Bakody, Stutter, Seider, &c. whom Simon quotes. It is a question of evidence; and "S.'s" is of the worst hearsay description we have lately met with. We quote none but Hahnemann himself, and the disciples whom he vouches for in his books.

"R." shall be attended to.

"E. C. P." should give his name, as the "Old Navy Surgeon" has, long since.

Communications have been received from Dr. Ashwell, Mr. Noble, Dr. Kemp, Mr. H. L. Smith, Mr. Pritchard, Mr. Hulbert, "Z.," "Hibernicus."

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XII.

Medico-legal illustrations of Rape—German and Italian cases—Analysis of the celebrated Thornton and Ashford trial—The prosecutor's statement and prisoner's defence, how far borne out by the circumstances—The medical evidence, with remarks—General evidence—The alibi—Probable cause of Mary Ashford's death—Margaret Patterson's case—Violation with horrible cruelty—STUPRA CONTRA NATURAM—A few remarks on unnatural crimes, and the extent of proof of which they admit.

THE medico-legal report with which I closed the last lecture, seemed well adapted for an illustration. It served to show the systematic careful method usually pursued by French medical jurists, investigating a case of alleged rape; and so well does every point seem to have been attended to in that instance, that there appears, indeed, to be nothing left to desire. The Germans, also, have their regular forms for reporting in rape and other cases, and I could have wished to present you with a specimen of their mode of proceeding; but I find that the examples supplied us, even by some of the most recent authorities (Dr. Bernt, for instance, who brought out a new edition of his *Viss Reperta* only a few months ago), are somewhat musty—dated as far back as 1783 and 1791.

Italian case of alleged rape and infection.—We are indebted to Dr. Beck for the particulars of an interesting Italian case, which involved more than the mere ques-

tion of violation. Signor Crespi, a young man of good family, at Rome, was charged with a rape committed on a girl under the age of puberty: he was arrested, and the girl examined by three physicians and two surgeons. The report was, "that the sexual parts were altered and tumid; that the hymen was entirely wanting, and the whole of the vagina was irritated, inflamed, and of a deep red colour—particularly so at the point of the frænulum." The vagina was dilated so as to admit a finger with perfect facility; and, finally, they observed a copious discharge of purulent and sanguinolent matters. The medical examiners were of opinion that the complainant had been deflowered recently, and that the discharge arose either from mechanical injury or actually from a communicated gonorrhœa. The girl herself stated that the discharge began immediately after the rape: it did not yield to the ordinary antiphlogistic treatment; and subsequent examinations by the same physicians induced them to lean more strongly to the idea that it was of venereal origin.

The accused was convicted. But Professor Metaxa took up the case, and argued two points—that there was not sufficient evidence of the rape, and that the girl laboured under leucorrhœa. Respecting the first, his position was general,—the difficulty of the proof derived from apparent absence of virginity; and it was urged that a rape committed on a female under puberty would have left more positive marks than were observed in the present case. His observations on the second point were more conclusive: he maintained that the nature of the discharge ought to have been better ascertained; gonorrhœa only affects the inferior and more external parts of the genitals, while leucorrhœa proceeds from a higher source: if the parts, therefore, had been washed carefully, and then again inspected, no mistake could have occurred. He argued further, that gonorrhœa has its regular period of high in-

inflammation and decline, while leucorrhœa is often chronic, and increases and diminishes at irregular intervals. The statement that the discharge began immediately after the alleged violence, he insisted was opposed to the idea of its being venereal.

Some other circumstances mentioned in the report were also criticised by the Professor; such as the assertion that the parts were acutely inflamed, while it appears they could be handled without giving pain; and it seems there was no hæmorrhage of any kind, nor was there any account even of carunculæ myrtiformes in the absence of the hymen. Testimony was also produced that the girl did actually labour under leucorrhœa.

So strong a representation of all these facts and inferences was presented to the authorities, signed by twenty-eight other professors and physicians of Rome, that it led to a reversal of the sentence. Dr. Beck concludes his notice of the case by assenting to the shrewd observation made by a reviewer, in an American journal, that the Professor, while he certainly showed that the physicians were wrong in supposing gonorrhœa, weakened his arguments not a little by insisting so strongly on leucorrhœa; for, admitting that leucorrhœa was present, there seems to have been quite enough of indicia of violence observed about the sexual organs to warrant the probability of rape. Signor Crespi must, therefore, be considered as having escaped through the remissness of the examiners in ascertaining a collateral point of testimony.

The celebrated Warwickshire trial—Thornton and Ashford case.—I shall now beg to call your attention to a very celebrated English case, which created an intense interest in the public mind about nineteen years ago, and some of the circumstances connected with which have not to this hour been explained. A young woman was found drowned, with recent marks of deforation on her body. Suspicion of rape and murder alighted on a man who had been seen in her company only a few hours before her death, and who acknowledged afterwards that he had had connexion with her: he was indicted and tried for both crimes, but acquitted—the evidence not satisfying the minds of either judge or jury.

The popular voice, however, pronounced Thornton, the accused, guilty, and his escape from condign punishment was attributed to the mere technicalities of the law. A second trial was loudly called for; and it appears that, according to certain ancient statutes, the nearest of kin of the deceased had a right to *appeal*. The brother of the deceased was, in this instance, induced to appeal;

whereupon the appellee claimed a *trial by battel*. It was gravely argued in the Court of King's Bench, whether this sort of trial should be permitted. The proceedings occupied several months. Battel was ultimately granted, but declined by the appellant; whereupon the prisoner was permitted to go at large.

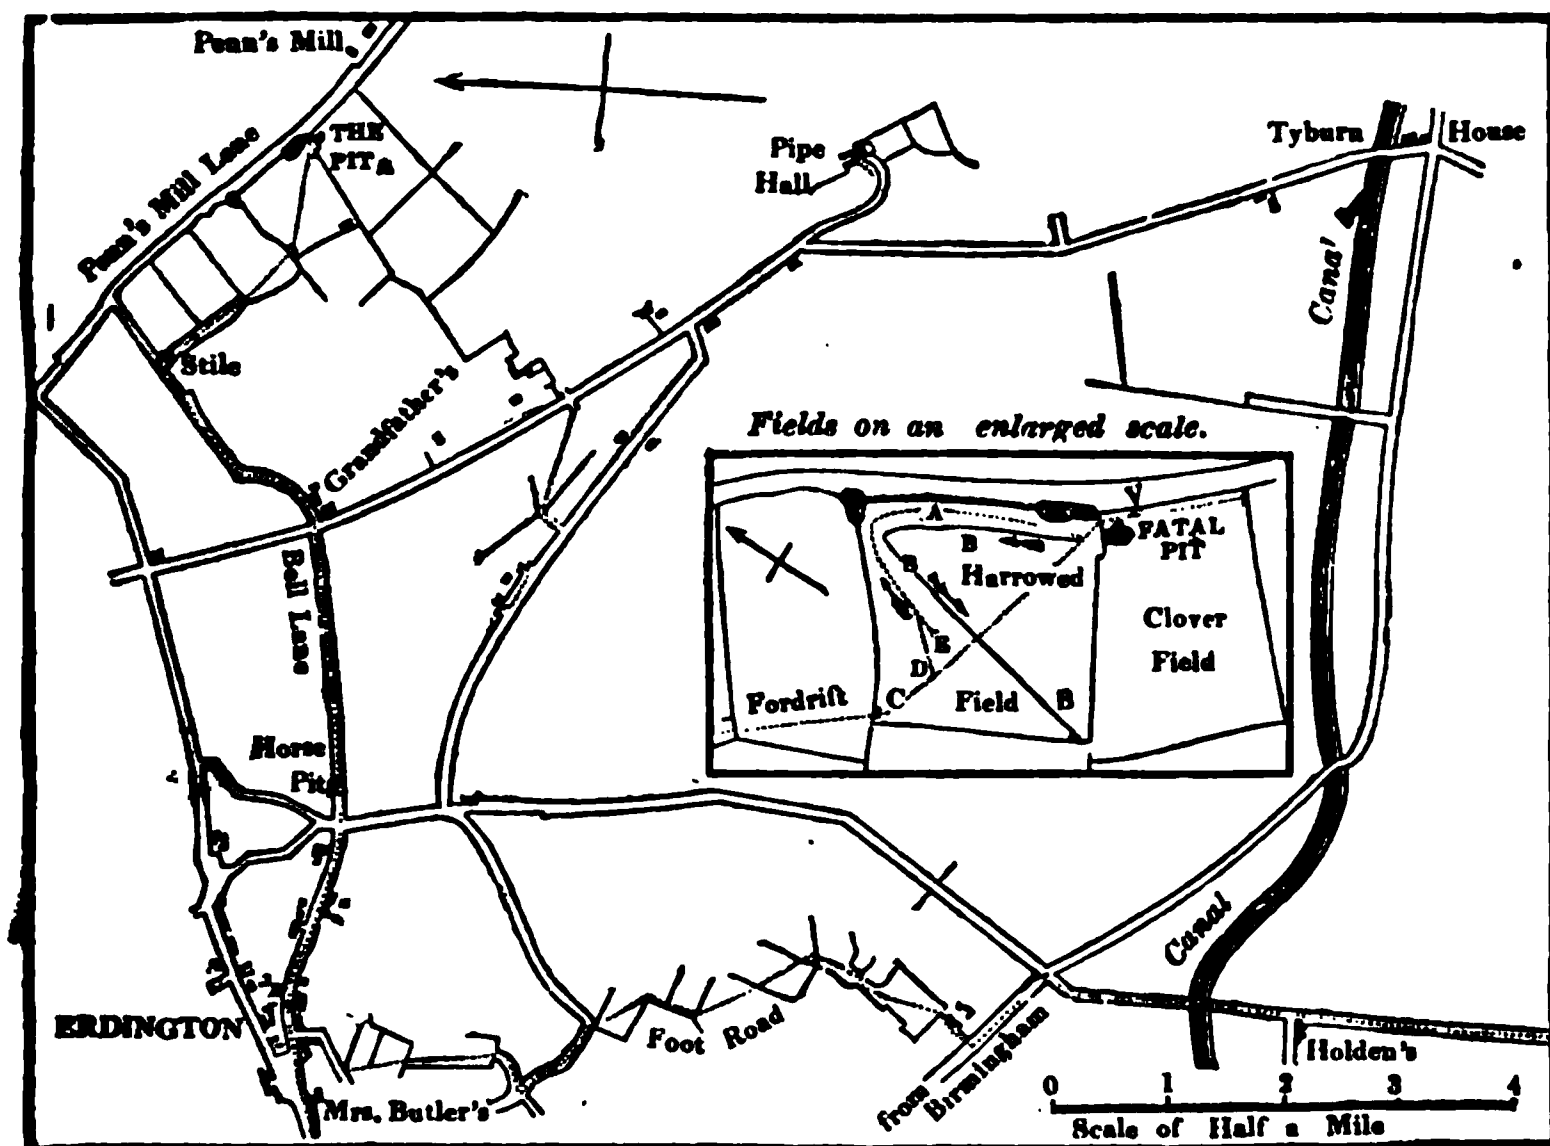

Let us review the principal circumstances of this case, for they are worthy of our best attention. I shall take, in the first place, the statement of the prosecutor's counsel, as it will serve to represent the popular side of the story. We shall then compare with it the prisoner's statement, and see how far each was borne out by the evidence.

Prosecutor's statement.—After the usual preliminaries about the heinousness of the crimes with which the prisoner, Abraham Thornton, was charged, counsel proceeded. The deceased, Mary Ashford, was a young woman of engaging manners, handsome in her person, and of unblemished character. She was well known in that part of the country—that is, at Erdington, and in the neighbourhood; her parents were poor, and she lived with her uncle, a farmer at Langley. On the evening of the 26th May, 1817, the deceased went with her friend, a young woman of the name of Hannah Cox, to a dance at a public-house in the vicinity of Castle Bromwich, called Tyburn-house. Thornton was there, and was much struck with her appearance: he inquired who she was, and on being told it was old Ashford's daughter, he said, "I have been connected with her sister, and I will with her, or I'll die by it." He danced with her in the course of the evening, and about twelve o'clock, when she left the house for the purpose of returning home, he accompanied her. Hannah Cox also went part of the way with them; but after she parted, there is no account of prisoner and deceased till three o'clock in the morning. At that hour a man saw them sitting together on a stile, when Mary Ashford appeared anxious not to be recognized. At four o'clock she called at Mrs. Butler's, where Hannah Cox slept. There she changed her white dancing dress for the red spencer, pink frock, and black stockings, which she had worn the day before, put her other things in a bundle, and left for home at about a quarter past four. She was in good spirits, and cheerful in talking to her friend Hannah on this occasion: said that Thornton had stopped with her a good bit; and that she had slept at her grandfather's. [This last assertion was wholly untrue.] Soon after leaving Mrs. Butler's, deceased was seen going up Bell-lane on her way home. It was at this time at least a quarter past four. At half-past six,

her bundle, her straw bonnet, and her shoes, were found beside the pit from which her body was soon after dragged; so that between a quarter past four and half-past

six, the murder with which the prisoner was charged must have been perpetrated.

In the harrowed field, adjoining the one in which the fatal pit is situated, were ob-

served the footsteps (D, E, A) of a man and woman. They were off the foot-path (C) which led through these fields to Langley. These footmarks were those of two persons now running, now dodging, and again walking, and were found to lead to a spot (V) where there was an impression of a human figure extended on the ground. In the middle of this impression was a quantity of blood; at the bottom of the figure there was a still larger quantity; and from this to the pit traces of blood could be plainly detected. Now the footsteps in the harrowed field were evidently those of Thornton and Mary Ashford, for the shoes they wore were compared with the impressions. There was the mark, also, of a man's foot at the edge of the pit—the left foot, slanting, the outside pressing deeper than the other, as if made by a person who had leaned forward to throw something into the water. [This footmark, however, was not shown to be Thornton's.] When the body was examined by two surgeons, the proofs of deforation were clearly made out; and it was said that there were marks of violence on each arm, as if caused by the grasp of a man's hands while holding the deceased down on the ground. The prisoner confessed that he had been with the deceased till four o'clock in the

morning, and that he had been connected with her, but with her own consent. His clothes confirmed the fact of the connexion; and hers, found on the body, were stained with blood and dirt.

Such were the leading facts in the case for the prosecution: the obvious inference from which would be, that the violation had been effected after the deceased had been seen alive for the last time, and that she was then murdered. The crimes were laid to Thornton's charge, as he had expressed his intention to have carnal knowledge of the deceased, and had been seen in her company so late as three o'clock: he acknowledged, indeed, himself, that he had been with her till four.

Account of Thornton.—It will now be proper to state what account the prisoner was able to give of himself; and perhaps it may be as well to premise a few words relative to Thornton's person. To such a height did the public indignation carry all those who had not seen the man, that they believed him to be "a bloated disgusting-looking person," at least twice as old as Mary Ashford (who was twenty), and likenesses of the parties were sold in all the print-shops, shewing, of course, as much contrast in their respective physiognomies as possible;—he all ugliness, she a Venus; in fact, it was

a sort of "beauty and the beast" affair. Those, however, who were enabled to satisfy their curiosity by a sight of the monster (as thousands did when he was brought up on successive occasions at Westminster), found that he had been unfairly dealt with; and he is described by eye-witnesses as "a stout, well-looking young man, about five feet seven in height, with a fresh complexion, and appearing to be not more than twenty-five or twenty-six years of age." He was the son of a respectable builder at Castle Bromwich, and worked at the business as an assistant to his father.

When, on the morning the body was found, the circumstances were canvassed on all sides, it was suspected immediately that Thornton was implicated, and steps were taken to have him apprehended. Daniel Clarke, the publican who kept Tyburn-house, went over to Castle Bromwich, where he met the person he was in quest of, riding on a pony along the turnpike-road. I shall quote the evidence of Clarke. "I asked him what became of the young woman who went with him from my house last night? He made no answer, and I told him she was murdered and thrown into a pit. Prisoner said, Murdered! I said, yes, murdered. Prisoner said immediately, I was with her till four o'clock this morning. I asked him to come along with me to clear himself; he went with me to my house, better than a mile; he said he could soon clear himself; he said nothing more about this; we were talking about farming and the like. He put up his pony; he said he should walk afoot to Sutton. He went into the room and had something to eat and drink; he might remain there half an hour; he staid in the house till the constable came. I did not offer to discourse about the murder afterwards, although I was very much shocked. I did not know that the prisoner had been with her till four in the morning, till he told me. I thought he appeared a little confused when I first put the question to him."

Prisoner's statement.—On being taken before a magistrate, Thornton made a voluntary deposition to this effect,—that he had been at the dance the evening before, and stayed till twelve o'clock; that he then went away with Mary Ashford and two others; that after the latter had left them, he and Mary Ashford went on as far as Mr. Freeman's [marked in the map as Grandfather's]; they then turned to the right, and went along a lane [Bell lane] till they came to a gate and stile on the right hand side of the road; they went over the stile, and along the foot-path across four or five fields—could not say how many. [Here

the fact of the connexion seems to be implied in the prisoner's examination—nothing is stated; he then continues—] Examinant and Mary Ashford then returned the same road; when they came to the gate and stile they first got over, they stood there ten minutes or a quarter of an hour talking; it might be about three o'clock. While there a man came by, to whom examinant said "good morning!" and the man said the same; he (Thornton) and Mary Ashford stayed at the stile a quarter of an hour afterwards; they then went on together towards Erdington, (within a short distance of Mrs. Butler's), where he parted with the girl, and never saw her after. He waited for her about five minutes, expecting her return; it was then four o'clock, or ten minutes after four. Examinant then went by the foot-road home; passed Shipley's; afterwards went by Holden's, where he saw some people busy about cows; then came to the flood-gates, on the way to Twamley's mill, where he saw the keeper, whom he knew, and of whom he inquired the hour; it was near five o'clock; and so on, he described his journey home.

Now every part of this statement or deposition capable of being verified by collateral testimony, was found correct: the other part rested on the same sort of presumption on which the alleged circumstances of the murder rested. The question was, which presumption was the stronger.

Circumstantial evidence.—There cannot be a doubt but that Mary Ashford was in Thornton's company, alone, from shortly after twelve till three in the morning. This included the dark part of the night: it was clear day-light by three o'clock, and people were up and stirring, going to their work by four, or soon after. Was the defloration effected within those three hours, or not till half-past four or later? In other words, did Thornton exercise all his arts of seduction in vain during the period which was in every way most opportune for him,—or did he way-lay her on her road home, violate her, and then murder her by drowning, all in open day-light, and beside a frequented foot road?

Mary Ashford changed her dress when she called at Mrs. Butler's. If the sexual intercourse took place before this, would she have been in good spirits and cheerful, as her friend described her,—would she not have complained,—and would not her dancing clothes betray the treatment she had met with? As to the first, it is clear that she dissembled with her friend: she also told her what was not the fact—that she had slept at her grandfather's, and concealed the circumstance of her having

parted with Thornton only shortly before. But the evidence connected with the clothes is worth observing. The gown, petticoat, and white silk stockings (her dancing dress), which she took off at her friend's, and there wrapped up in her bundle, were exhibited to, and examined by, the jury at the trial. They were all bloody: the stockings particularly were stained all the way up. It is true that the frock she then put on, was found very bloody also in the seat part behind; but the black worsted stockings worn at her death were not bloody, but quite clean and unstained, except one little round spot of dirt on one of them.

That she had the menses on her, and that, too, profusely and unexpectedly, that morning, is certain: she also lost a great quantity of blood in consequence of the defloration. Now it is very remarkable that she never told Hannah Cox the state she was in, if it were only in respect to the menstrual discharge: nor is it easy to conceive any motive for concealing it, unless in connexion with other points to be concealed also.

The medical evidence.—I shall read for you the medical evidence given by Mr. Freer—taking occasion to observe, that it is perfectly authentic in the form in which it is here reported, being, in fact, the judge's notes of what fell from the lips of the witness.

“Mr. George Freer, examined:—”

“Is a surgeon at Birmingham; went on Tuesday [27th] to the coroner at Penn's Mills. Examined the body at night, at half-past seven o'clock. Had a cursory view of the body. Being night, *I reserved the examination for another day.* I observed the body was placed in a very dark and small room: it was removed into a larger room. During the time of its being removed, I went to examine the pit. When I returned, *they had undressed it, and just washed off the upper surface.* Between the thighs and the lower part of the legs was a great deal of blood; the parts of generation were lacerated, and a quantity of coagulated blood was about those parts. *It was getting dark, and I deferred the opening of the body till Thursday morning.* On Thursday morning I proceeded to open the body, and found the parts of generation lacerated; some coagulated blood about them; and she had the menses upon her. I then opened the stomach, and found in it a portion of duck-weed, and about half a pint of thin fluid, apparently chiefly water. In my judgment she died from drowning. Two lacerations quite fresh. I was perfectly convinced (that) till these lacerations she was a virgin. Some coagulated blood adhered to them. Saw the coagulated blood on the ground. The menses do not produce such blood as that. The coagu-

lated blood proceeded from the lacerations. The lacerations were from the sexual intercourse.

“Cross-examined.—Observed no marks of violence at all but what I have mentioned. Nothing in the coagulated blood or the laceration that would produce death. There was no laceration but what might or might not arise from sexual intercourse with a virgin, with consent and without violence. It is very evident that the menses came on at a very unexpected moment by her. It may increase a little for a day or two: may be less at first, and increase in an hour or two. It might become extremely copious and troublesome.

“Re-examined.—Dancing likely to increase it. About five feet four inches high: robust, fine young person. An unusual quantity of blood, independently of the menses.”

I cannot help here remarking, consistently with the principles and rules laid down in the preceding lecture, that there are some striking faults in the medico legal conduct of Mr. Freer. Upon his own showing, he did some things which, I should say, he ought not to have done. Why did he reserve the examination for *another day*? The alleged rape was committed early in the morning of Tuesday; he had an opportunity of making a personal inspection on the Tuesday evening: yet he put it off till Thursday! Surely this was not the way to go to work in order to detect sexual lesions. He also allowed the body to be *undressed*, apparently without directing any attention to the state of the clothes; and what is worse, he permitted the body to be washed,—“they just washed off the upper surface,”—without noticing the many appearances which possibly might have been observed in an early examination of the parts. But to return to the general evidence.

General evidence resumed.—The foot-marks in the harrowed field, and in the clover field, seemed to give damning proofs against the prisoner. But at what time were they made,—before or after the parties were seen at the stile? Thornton is said to have admitted at the trial that the evidence was correct respecting the foot-prints of the running, dodging, &c. (A.) towards the clover field; but he denied that the track (B) from that quarter towards the lower gate was his; and it is worth noticing, that the print beside the pit was not in any manner shown to be his: his left shoe was not compared with it, evidently because there was some obvious dissimilarity. And, by the way, concerning the foot-marks on which so much stress has been laid, long ere the requisite comparisons were completed, they were so confounded with the foot-prints made by

numerous visitors who came upon the ground, together with some rain which fell, that it became necessary to secure the identity of a few of the impressions, by boarding them over.

I shall not go through the details of the *alibi* set up by the prisoner. Two points in it, however, are so strong as to be almost conclusive. The last time Mary Ashford was seen by any of the witnesses was about twenty minutes past four, when going up Bell-lane alone; but Thornton was seen at Holden's, walking home leisurely, and by no means heated or hurried, at about half-past four. Now the distance from Mrs. Butler's (which Mary Ashford left at ten minutes or a quarter past four) to the pit, is one mile, two furlongs, and thirty-eight yards; and the distance thence to Holden's, by the shortest possible route, is two miles and two furlongs: so that the whole distance gone first by her, and afterwards by him (after the supposed murder) was upwards of three miles and a half. Is it at all possible that these three miles and a half could be traversed—all the running and dodging have taken place—the violation, the murder by drowning, and all inclusive—within *ten*, or at the very utmost *twenty* minutes, making every allowance for inexactness of clocks—which clocks, however, were, in the course of Tuesday, carefully compared? Now this is the difficulty in regard to the *alibi*, which must be got over by those who are not shaken by the other evidence.

But is it not an extraordinary question to ask, after all this, and asked it may certainly be without impropriety, whether there was *any* proof of murder in the case? There was none of rape: what was there of murder? It does not seem to have been proved that there was any killing even: there was, therefore, no *corpus delicti*. Yet, though there was no evidence of either murder or rape having been committed by any one, Thornton was tried for having committed both!

Probable cause of death.—It will always remain a curious speculation, how, if she were not murdered, did the unfortunate Mary Ashford perish? Was it by suicide, or by accident. Her shoes were very bloody: they must have been so when she put them on again after changing her stockings at Mrs. Butler's; for her black stockings were wholly free from blood. Those shoes were placed together at the brink of the pit with her bonnet and bundle, in such a manner as no murderer would leave them, even if he wished it to be considered a suicide, for their bloody appearance must necessarily lead to further inquiry. There is a bare possibility, of the very slightest description, that she committed

self-destruction. Yet, supposing this to be the case, in consequence of some sudden fit of despondency seizing her on her way home, what could have induced her to take off her bonnet and shoes, and to place them so carefully as she did? On this fact it is, that a third, and, as I think, the most plausible conjecture as to the manner of her death, is grounded. I shall quote the words of an intelligent and learned gentleman (Mr. Holroyd, son of the presiding judge) who wrote the most clever pamphlet which appeared on the subject, and who seems to have first suggested this mode of accounting for the death of the deceased. "In her bundle were her half boots, the only part of her daily dress which she had not resumed. One of her dancing shoes, with which she was returning home upon her feet, being all blood, and the other bloody, who can say whether, startled with observing as she walked, that blood upon it which would be visible to persons meeting her upon the road, and to her uncle upon her return home, she might not have put down her bundle, and taken off her shoes and bonnet, in order to take out and put on her half boots instead of her bloody shoes? And what was more probable than that she should do so? If that was the fact, when the exhaustion and fatigue she had gone through in her walk to Birmingham and back again (12 or 13 miles) the day before, her dancing at night, her want of sleep and rest afterwards, the circumstances attending the connexion that had taken place between her and Thornton, her loss of blood, and want of nourishment, for none was on her stomach when her body was opened, what is more probable than that in stooping and turning to take out her half boots in order to put them on, on the top of a bank of a very sloping pit side, where the surface of the water was as much as four yards below the pit bank, she should, by an inadvertent step backward or otherwise, slip in, or turn faint and giddy, and so tumble in?"

In concluding this somewhat detailed account of so remarkable and mysterious a case, I cannot refrain from saying, that, in my opinion, the acquittal of Thornton was right. There was no evidence save of the defloration and death of the girl; of rape and murder there was none, except what was of the most loosely circumstantial nature. Thornton, however, had the guilt of the seduction and defloration, and no doubt, by implication, the death of the unfortunate girl to answer for; and if there be weight in the indignation of an insulted public, he has long ere this expiated his heavy offence. He was hooted from the society of his fellow men in this country, and

was obliged at last, I understand, to take refuge in America.

Margaret Patterson's case.—I mentioned, in the last lecture, the importance of examining the persons of individuals said to have been violated, with a view to finding *indicia* of violence and cruelty; which are sometimes found by searching the cavities—the mouth, for instance—where substances may have been introduced in order to prevent the victim from calling for help. But who could have imagined what was discovered in the body of an unfortunate woman who was brutally ravished some years since in Scotland? I allude to the affair of the Gilmerton carriers, who violated and murdered Margaret Patterson, in the year 1830. The details of the crime were too horrible for exposure to the public eye. At the trial, the proceedings were conducted with closed doors, and no report of the evidence has ever been published, or perhaps preserved. What we know of the nature of the crime committed is sufficiently shocking. The victim, an unprotected female, making her way on foot from Edinburgh to Dalkeith, was taken into their cart, by those villains, under the pretence of assisting her on her journey. There they violated her person repeatedly, and became so infuriated with their wickedness that they took stones from the road, coal, straw, prickly plants, and every thing they could immediately find, and forced them into the vagina. When she fainted and sunk under her tortures, they threw her out of the cart into a ditch by the road-side, where she was found next morning, with only life enough remaining to linger out three days of agony; luckily, however, with the power to disclose the names of her murderers. On examining the body after death, the substances just mentioned were found in the vagina and rectum—for both passages were broken down into one—the perinæum being dreadfully lacerated. All the abdominal viscera were in a high state of inflammation. I subjoin the Latin account of the horrid transaction, as it was given in the *North Briton* newspaper, by the learned editor, Dr. Browne:—

“Quum ii scelestissimi vehicularii, omnis nequitiae et immanitatis capaces, Diabolo suadente, foeminam, semel atque iterum, in vehiculo suo constupraverant, atque ita crimen raptus poena capitali puniendum admiserant, procul dubio est, ut in vaginam miserrimae lapides tres, iis similes quibus via publica strata est, carbonem, stramentum, gramen cum spinis quibusdam, injecerunt, osse thoracis nexilis, ut fistuca, utentes: quo facto, raptores, saevitia gaudentes, miserrimam e vehiculo

dejecerunt et postea corpus exanime in fossam juxta viam publicam abriperunt. Et plus triduo, id est dum Gilmertoni commorata est, ac etiam usquedum mors finem fecit miseriis, foemina haecce intra abdomen suum habuit lapides, carbonem, stramentum, gramen, cum spinis quibusdam, scelestissimis vehiculariis inferta, more nefando, per os thoracis nexilis, ut jam superius dictum est. Post mortem, dissectione corporis facta, omnia haec inventa aut in recto aut in vagina; perineum ita dilaceratum ut ex vagina et recto una tantum canalis facta, quod rarius accidit, etiam in parturitione difficilima; haemorrhagia fere continua, qua multus sanguis effusus et indusium penitus totum cruore tinctum; signa violentiae cruribus impressa; atque omnia intra abdomen inflammata.”

The two wretches were executed, of course; but it is only the punishment which some of the old feudal governments, most skilful in torture, would have inflicted, which could have been adequate to the enormity of their guilt.

STUPRA CONTRA NATURAM.

Multum mihi animo volventi utrum, cum de stupro violento dissererem, pauca quoque de vitio isto abominando contra naturam adjicere auderem, ita facere tandem visum est. Nam si omnem mentionem stupri istius omitterem, sic mecum reputavi, hiatus certe insignis in hisce sermonibus foret; et dein censendum, si apud auctores Germanos, Italos, et Gallicos, quorum in patria crimen violatae naturae leviter tantum vel non omnino punitur, attamen notatu dignum habeatur, quam multo fortiori argumento apud nos, quorum legibus hujus criminis damnatus capitali poena percutitur, de hac re nefanda verba facere necesse est. Idcirco salvo pudore, sub umbra doctioris linguae, παρρησιαζεσθαι liceat.

Casta severitas majorum vix nomen criminibus hujusce generis imposuit. Cum Langobardus quidam sceleris istius sodomitici accusatus esset (an. 50, Edw. III.), crimen ejus “peccatum illud horribile inter Christianos non nominandum” vocabatur. Hodierni tamen haud tam delicatis auribus vel lingua praediti sunt.

In praelectione penultima* locus statutorum recentium [9 Geo. IV. c. 31] laudatus est, in quo, crimen de quo agitur, proprio et nudo nomine appellatur. Et in sectione xv. ejusdem statuti flagitium abominabile cum sua poena apertissime denunciatur. Quisquis porro post annum suum decimum quartum scelus hoc commiserit capite damnatus erit, et suspendio

puniatur; et hoc, quanquam socius in amplexu abominabili, sine vi illata consensum dederit. Non obstante terrore legum, haud perraro casus istiusmodi in foro audiuntur: falso vel vere crimina individuis obijciuntur, et luminis quod medicina præbere nonnunquam potest magistratibus opus est.

Stuprorum nefandorum plurima genera recensentur: stuprum videlicet masculinum, inter marem et marem patratum, nomine *παιδεραστια* antiquis bene notum; stuprum scæminarum inter se, quod Div. Paulus in Ep. ad Rom. verbis igneis denunciat — antiquioribus pernotum ut *τριβαδικη ασελγεια*, recentioribus autem, quam familiariter, Nuptiæ Romanæ, vel Facetiæ Florentinæ, nuncupatum; dein stuprum cum cadaveribus, sicut inter Egyptios haud inusitatum fuit, nec, si quibusdam credatur, temporibus longe præteritis intentatum in aliis locis; et denuo, hominum (proh pudor!) cum bestiis. De uno alterove horum vitiorum, quanquam durum atque molestum de vitiis verbum facere quæ hominem infra animantia cætera deprimunt, pauca in medium afferre oportebit.

1. Quænam sunt signa quibus masculinum stuprum testatur? In judicando caute procedendum est; namque factæ penetrationis indicia haud facile pro certo attineri queant. Vel recens est stuprum vel vetustum; vel semel, aut saltem paucis vicibus, flagitium admissum est, vel in consuetudinem venit. Recentis flagitii documenta, ad iudicium probabile accedere possunt. Vetusti sceleris, et raro patrati, nulla signa supererunt. Si vetustum et consuetum, possibile est, inspectione partium, fidem circumstantiis aliter cognitis addere.

Audiamus quid dicit celeb. Orfila, satis audacter, ut opinor, hac de re ex cathedra loquens:—"L'ouverture du rectum présente chez les personnes entachées de ce vice la forme d'un entonnoir, remarque due à feu M. Cullérier, qui, en sa qualité de médecin de l'hospice des vénériens, n'a que trop souvent eu l'occasion de la vérifier. Le bourrelet de l'anús est gros, boursoufflé et lâche; le sphincter se contracte difficilement, et le doigt entre sans effort. Il est vrai que cette disposition de l'anús suppose en général un certain nombre d'introductions; mais la disproportion entre le membre viril et l'orifice peut être telle que la forme de l'ouverture du rectum soit changée, même par suite d'une première tentative. Des hémorrhoides considérables, des fistules profondes, le renversement, les squirrhe, et même le cancer du rectum; telles sont les maladies qui peuvent accabler les personnes qui se livrent habituellement à la sodomie."

Consilium idem auctor tunc addit, caute distinguendum esse, ne pro stupri nefarioris indicibus morbi venerii effectus sumantur. Namque rhagades, verrucæ, cristæ, mariscæ, ficus, in errorem facile inexpertum perducere possint.

Illustris ille Parent-Duchatelet nuper et nimis cito morte præreptus, in opere suo *De la Prostitution*, fidem nimiam signo isti a Culleriero monstrato reponere vetat; propterea quod nemo medicorum dispensatorii a se consultorum, neque DD. Jacquemin et Collineau, ne uno quidem exemplo in pluribus casibus ubi stuprum contra naturam in scæminis admissum fuit, istam intestini recti conditionem infundibiliformem compertam habuerant.

2. De vitio scæminarum quas Tribadum nomine appellant, vix quæstio in curiis oriri potest, nisi cum crimine alio scelus istud conjunctum sit. M. B. Valentinus insignem narrat historiam quæ "furens quid scæmina possit" exemplo memorabili docemur:—"Scæmina sexum virilem diu mentita tandem aliam sibi conjugio maritali, et, horrendum dictu! copula sacerdotali jungi curavit; cui ut se virum præstaret, membrum virile artificiale, femoribus et inguini alligando, et cum amasia sua consuescendo muliebria hujus tantopere exercuit, ut tandem miserrime violata nefandum facinus consanguineis primum, et abhinc magistratui publico detegere necessum habuerit." Facinus de quo loquitur Valentinus Facultati juridicæ Giesseniæ relatum est anno circiter 1721 ut de pœna consultum esset; nam rea convicta crimen confessa est et pœnam tunc temporis quo Valentinus scripsit, expectabat.

3. Quandoque consortii carnalis cum bestiis, nempe equabus, vaccis, canibus, suibus, gravis suspicio oritur. In talibus casibus nefandis, vix fides adhibenda est, nisi complures testes asseverent se flagitium vidisse. Attamen si ex inspectione animalis probamina criminis magistratus colligere velint, quærant veterinarios. Casum brevem, in quo per indicia super corpus animale visa crimen detegebatur, adjungere liceat. Albertus Meckel in suo *Lehrbuch* rem hisce verbis narrat:—"Ein junger Hirt missbrauchte kürzlich eine Kuh; die That wurde entdeckt, weil die Geschlechtstheile der letztern in Entzündung geriethen, und das Thier erkrankte. Der Grund dieser Erscheinungen lag jedoch keineswegs in der *mentula* des Knaben, vielmehr darin, dass letzterer, weil er Schwangerwerden des Thiers befürchtete, dies zu verhüten, einen Stock in die Geschlechtstheile geschoben hatte!" De stupro cujuscunque generis, hactenus: tantum.

CLINICAL LECTURE,

Delivered at St. George's Hospital, December 2, 1836,

By DR. SEYMOUR.

PURPURA HÆMORRHAGICA.

I PROMISED to speak to you to-day respecting a case which is one of considerable interest, from the great obscurity which exists regarding the cause of the disease.

It is that of a man named WARD, who came into the house some time back, labouring under purpura hæmorrhagica. He went out apparently well, but subsequently returned, and has since died.

Now what is purpura hæmorrhagica? The name is applied to an ecchymosis, or an effusion of fluid under the cuticle. This occurs sometimes in very large spots towards the end of malignant fever, and it occurs likewise without any fever being present. Sometimes there is not only effusion under the cuticle, but it extends over the whole surface, and to a number of the mucous membranes. There is bleeding from the nose, bleeding from the mouth—a sort of exudation of blood into the mouth, the stomach, and the intestines: this sometimes occurs without an effusion under the skin, and sometimes with it. Sometimes, under these circumstances, very large quantities of blood are passed from the kidneys, sometimes from the conjunctiva of the eye, and from the membrane lining the ears.

It is observed under very different circumstances. The most frequent form of purpura is accompanied by a languid pulse, and there is a great tendency all over the body, on the occurrence of any accident, to the extravasation of fluid from the vessels: this would appear to be particularly the case in the last stages of fever. These petechiæ, vibices, or whatever name you choose to give them, arise from a weakened condition of the circulation in the capillary vessels, and, as we may well suppose, a dissolved state of the blood. The blood drawn in this disease does not coagulate in the same manner as under ordinary circumstances; it does not separate. When persons die from these hæmorrhages, they often expire from a great quantity of blood being extravasated upon a vital organ—the lungs, the liver, or the surface of the brain. A case occurred not long since to Dr. Macleod of this disease, in which after death a clot of blood was found in the brain. Dr. Elliotson mentions one or two cases in his lectures, which proved fatal by an effusion in the brain.

But there is another form of the disease, where, instead of the circulation being diminished, it is greatly increased.

This man, WARD, was admitted on the 14th September, with an eruption of purpura about the arms and lower extremities, coalescing over the feet. At the time he was admitted his mouth was affected by mercury. It was clear that he had laboured under some degree of dropsy from enlargement of the heart, and he had been put upon mercury with a view of diminishing some inflammatory action which was supposed, and which undoubtedly did exist. When he was admitted the first thing was to cure his mouth, and he was then put on mineral acids. Three drops of carbonic acid, and two drops of nitric acid, were given in an infusion of orange peel, two or three times a day. In all extravasations of blood, the acids have been considered particularly useful.

Some persons perceive an analogy between this disease and sea scurvy. Sea scurvy is attended with this extravasation of blood; but there is extraordinary weakness of the constitution, the gums are spongy, the teeth fall out, the bones soften, the muscles also become soft, and under the skin are effused these purpura spots upon which we are speaking. Some persons have consequently thought that the purpura seen on shore must arise from a similar state of constitution; but this is quite a mistake. There is in the majority of cases, so far as I can see, no sort of analogy. The fact is quite notorious, that since the taking of vegetable acids by the fleets and armies abroad, scurvy has been almost entirely unknown. The disease used to carry off and destroy the crews of whole navies, but it has now become most rare where the sailors are provided with fresh lemon juice—and which is taken out for the purpose—or where they can procure fresh vegetables of any sort. The vegetable acids have been likewise prescribed with the same view in this disease; but inasmuch as these affections differ, we cannot expect they will produce the same effects.

The mineral acids have been thought useful, as giving tone to the circulating system, while at the same time they purified the blood. That was the idea, but of late we have heard that this is all wrong; that so far from its being the case, it is the neutral salts which are to act on the blood, and restore it from a black to a florid colour. Till the experiments on scurvy have been proved to be fallacious, we shall hardly fall in with this hypothetical idea. When I was physician to the Hospital Ship, I saw many cases of scurvy, and I never met with one which resisted the in-

fluence of vegetable acids. It is true that taking fresh meat, or taking fresh vegetables of any kind, will cure the disease, and free the patient from the state of body induced by being kept on salt provision; but it is quite clear, that if the acids act by turning the blood black, and the neutral salts by returning it to its florid condition, the quantity of acids given would not cure the disease—the disease would not get well under them; on the contrary, the introduction of acids into the system would make it worse. This, however, is not the case. If it is a problem at all, it must remain so, till we are enabled to prove that sea scurvy is cured in some extraordinary manner by alkaline remedies just as well as by acids—an experiment which, I think, is not likely to be tried.

WARD took this medicine some days, and the eruption decreased remarkably, and his mouth was now well; and arguing from the opinions which exist on the nature of the disease, from his face having been swelled, from the white appearance of the whole body, and the spots disappearing, instead of putting the acids into an infusion of orange peel, I ordered them to be put into a decoction of bark, with a little tincture of bark. This disagreed with him; he could not bear this quantity of stimulation, and I was obliged, of course, to discontinue the bark; but he went on with the acid; and finding that the action of the heart and arteries increased, I bled him, and the blood was buffed and cupped. I bled him a second and a third time, and the blood still presented the same appearances, separating into the ordinary coagulum which occurs in inflamed blood, with a considerable quantity of buff on the surface. This is a very different condition to that of the state of purpura, in which the vessels pour out, as it were, a fluid perfectly altered in its composition.

On the 22d, a very slight portion indeed of the eruption remained; he had gained very great strength, and was dismissed. He was re-admitted on the 21st November, and therefore he had been out just a month, during which time, I should mention, it appeared he had been taking bark. It would appear that he returned with the eruption more conspicuous than ever all over the thigh and leg; he had a good deal of difficulty of breathing; there was pain of the head; and the pulse was hard and 120. There was now a considerable diminution of urine; so that, instead of putting him on the acid as before, I ordered him a diuretic draught of nitre, and kept his bowels open. He was bled again to twelve ounces, and the blood drawn was buffed

and cupped, but not to such an extent as would induce you to repeat the operation. The coagulum was very firm, there was a large proportion of serum, and the buff surface was very much lessened; nevertheless, away went the eruption; it was hardly possible to discover it.

This was on the 23d; the purpura was scarcely visible, and some difficulty of breathing began to take place; and on the evening of the 24th he had a shivering fit, which was followed by great dyspnoea, and some degree of indistinctness. The breathing was somewhat of a stertorous character, but at the same time not such that people are generally subject to when there is any indication of increased action. I believed that effusion was taking place to the brain; but not thinking from the last appearances that he would be relieved by more bleeding, I ordered a blister to be applied between his shoulders, and a turpentine injection to be given. The blister rose indifferently, but on the following day he was better. He seemed to be greatly relieved by the injection, and it was repeated at night, though without avail; and he died on the 28th.

He was examined the next day, and many of you were present. All the symptoms were those of a person labouring under effusion in the brain; but there was no effusion of blood, nor was there extravasation of blood in any part of the body, neither had the muscles or the brain more bloody points than natural, nor was determination of blood apparent to any viscus. The brain was firm and white, and the fluid poured out perfectly clear and pellucid; not at all stained with blood, as is sometimes the case under these circumstances. The heart was enlarged, dilated, and flabby; and the valves, particularly the tricuspid valve—which is very uncommon—were thickened by that kind of deposit which, when it exists to a great extent, renders the arteries inelastic, and presents some obstruction to the flow of blood from one cavity of the heart to another. This is all that can be said of this disease as to the particular appearances.

There are certain circumstances connected with purpura which I shall mention, because they occur in other complaints, such as the subsidence of the eruption, and in some cases internal inflammation. I was much struck with a case which occurred some years ago. A man applied to me who had a large spot of purpura in the face—not a *nævus maternus*, but a regular spot of purpura. He was put on mineral acids, as usual, and I think he was occasionally bled. By this treatment the spot disappeared in a few days, but a violent attack of inflammation

of the pleura came on. He was bled repeatedly, put on mercury, and eventually got well of the pleuritic attack. Soon afterwards the purpura in the face re-appeared; he was again put on mineral acids as before; the purpura disappeared, and inflammation of the peritoneal covering of the bowels came on, from which he died. As soon as the purpura disappeared, these symptoms of internal affection began to take place. In the present case the effusion of blood upon the extremities, and into the cavities, took place in both instances connected with an enlargement of the heart; so that as soon as the extremities of the capillary vessels ceased to pour out this quantity of blood, they began to pour out water. The same thing occurs frequently in dropsy from enlargement of the heart. Where the dropsy has ceased, where the effusion of fluid which relieves the circulation no longer goes on, a vessel ruptures. These cases are of constant occurrence. There is a woman in the house at this instant, who has laboured under dropsy: there was no longer any effusion; the heart was beating over a considerable surface, and in three or four days she had a fit from effusion into the brain. She was largely bled; and after the second bleeding she came out of the fit. The lower extremities then became swollen; the cellular membrane filled with fluid; that was followed by relief, and she has since been better. But when the vital powers cease to make the dropsy, which is the relief of the symptoms, then great fear is to be apprehended of the rupture of a vessel.

I have seen similar cases to the one before us in young persons, and I have known them recover. A boy of 13 years of age came under my care: he was taken with what is called *cramp* in bathing. Some time after he was covered with spots of purpura, some of which were very large, and the heart was beating violently. I treated him as I should a case of inflammatory action of the heart; the inflammation was removed, and he got perfectly well.

There are two reasons for giving the turpentine injection. One is, that it is exceedingly useful in cases of serous apoplexy in making a determination to a distance. Stimulating injections are sometimes peculiarly useful under such circumstances; but in reference to this particular instance, turpentine is considered more especially useful where there is a transudation of blood from the vessels,—where it escapes in small quantities, as we see here; or in large hæmorrhages, particularly from the intestinal canal, there is no remedy so useful as the oil of turpentine. In the case of hæmatemesis,

vomiting of blood from the stomach, it exercises apparently almost a specific influence. I have seen cases where two or three doses cured the complaint. A man was brought on board the Hospital Ship, who had lost a large quantity of blood in this way. He was ordered two drachms of oil of turpentine and two drachms of castor oil mixed up in a mucilage, and two table-spoonsful were given three or four times a day. In two or three days no blood made its appearance. No blood was ever brought up again from the stomach, and none made its appearance except that which had been swallowed and digested. In bleeding from the intestinal canal, a portion passes downwards; it undergoes a certain degree of the process of digestion; and is exactly like soot. Some people call this *melæna*, because they want to give it a name. It is a blood which has been swallowed, and which has been operated upon by the digestive process. This will go on for several days after hæmorrhage to any extent has occurred from the intestinal canal. I saw, in conjunction with Dr. Lee, an artist who had brought up blood, and who had been treated by calomel and other medicines, from a suspicion that it arose from an undue secretion of the liver. I was shewn half a wash-hand basin of blood. He took turpentine, and for several years I heard no more of the case. Last year he had another attack of vomiting of blood; he again took turpentine, and the complaint disappeared.

There is a case which I have seen within two or three streets of the hospital, where twice within six months the patient has vomited blood, and in both instances, upon taking oil of turpentine, it immediately disappeared. It would seem that in intestinal hæmorrhage, whether it arises from a breach of the surface or an exudation from the vessels, the oil of turpentine has a considerable influence in stopping it. I do not know that here we have an evidence of its stopping purpura because that disappeared, but I made choice of a stimulating glyster from its being so useful, rather than any other under the effusion into the brain which had taken place. It is quite certain that this man laboured under organic disease of the heart. So long as the dropsy occurred in the first instance he was relieved by it; when the dropsy disappeared, this purpura came out; and when the purpura was cured by remedies, serous effusion took place into the cavities of the body. This is the only explanation I can give of this case, though it does not explain all the phenomena which occurred. There are cases in which the capillary vessels pour out fluid instead of blood, dependent upon a diseased condition of the

heart, and which are much relieved by the secretion. The effusion from the capillary vessels induces what is called *dropsy*, and most generally in the cellular membrane. But with regard to purpura, the circumstances are much more difficult to be explained.

Where purpura accompanies the last stages of fever, stimulants are applied, and opium and camphor are the best combination with which I am acquainted for such purpose, together with wine. I remember seeing a case of petectual fever in a whole family. Two out of three of the patients owed their lives to the stimulus of opium, camphor, and wine. It is rare that you will see such cases, but it is scarcely possible to keep the patient from sinking. The same thing no doubt occurs in ordinary cases. The state is one of a great diminution of the powers throughout the system, and the vessels not only pour out this fluid from the mucous membranes of the body, but likewise into the vital organs of the body; and it would appear that most frequently this viscus is the brain.

There is a predisposition which we know nothing about, which is termed the *hæmorrhagic diathesis*. Certain people are constitutionally more disposed to bleed than others. Sir Benjamin Brodie relates a case of father and son, both of whom died from the extraction of a tooth. Some persons are very liable to a bleeding from the nose in a most alarming degree. In some cases purpura is present; and in some, hæmorrhage exists without purpura, either from the nose, the mouth, or the urinary organs; and sometimes purpura precedes the attack. It must be looked upon as the same disease.

Where fluid is effused under the cuticle, and hæmorrhage takes place in great abundance from some of the mucous membranes, some authors have attributed this form of the disease to the spleen. Many years ago, I saw a boy, twelve years of age, who laboured under epistaxis, accompanied with purple spots: the bleeding from the nose occurred to a great degree. He was bled, purged, and saline aperients were exhibited; and he got better, and remained so for some time. The epistaxis then returned, and nothing stopped it—neither bleeding, ice, nor plugging the nostrils. The patient bled to death, and even in his last moments blood squeezed out of the nostrils. On opening the body, no membrane was found to have given way; the Schneiderian membrane was more vascular than usual, as if the patient had had a severe cold, but that was all. The spleen, however, was three-fourths decomposed; it could not be col-

lected. You will find several cases on record, of this disease connected with purpura, where it was found that the mass of vessels constituting the spleen were in a state of decomposition. Some persons suppose that the two facts may be connected, but the intermediate chain of reasoning no one can supply. When the disease is attended with a low condition of the system, it is supposed by some to arise from a weakness of the arteries, and others believe it to arise from an alteration in the composition of the blood itself. One does not exactly see how this should cause the exudation of blood on the surface. A third idea is, that it is connected, somehow or other, with disease of the spleen. No one knows what is the use of the spleen. It is a congeries of blood-vessels, largely supplied from trunks of arteries, and may be removed with impunity from the bodies of animals. It has been the fruitful source of a great number of theories, even down to our own times. Sir Everard Home suggested that the spleen was the organ through which substances passed into the circulation without going through the digestive organs, lymphatics, and thoracic duct; and thus accounted for diuretic substances being found in the urine so soon after they were swallowed; but he did not make out his case. Descartes, I think (at any rate, some philosopher), thought that its object was to keep the rest of the organs of body safely packed. Of late years, we have been told that it is the means by which warmth is preserved in the body in hibernating animals; that it is a sort of human warming-pan. The fact is, that no philosophical explanation has yet been given of its object. That it is a congeries of blood-vessels there can be no doubt, which, during the period of digestion, are more turgid than at other times; and some suppose that it is provided with super-abundant blood, as a reservoir during the period of digestion. It is quite certain, that in some of the cases of which we have been speaking, the spleen has been found in a remarkably unhealthy condition, and even allowing that it is of no use in the ordinary state of the body, in a diseased state it must be a very disagreeable addition to it.

I should state that I have seen persons recover, in a condition very similar to that which existed here, in which the blood has been inflamed, and the action of the heart and arteries has been very great. So I have seen persons recover who have been treated, in an opposite condition of the system, by stimulating remedies. I went, some years ago, with Dr. Locock, to see a woman, advanced in pregnancy, who had met with a fright, and soon afterwards

urage of purpura took place over . She was in a very low state. ls were freely opened, and a feel- exists, among some physicians, ated purging will cure the com- I have seen it tried in two or tances, but never with success. t see how repeated purging can n curing such a disease. GOUT.

al cases were admitted on Wednes- but unfortunately not any of them

are of very great importance. I will, however, state what they are.

There is one which is something similar to those of which we have been recently speaking—a case of gout. It is in a man named GRAVES, in King's ward, who complains of pain in the knees, attacking him sometimes with so much violence as to cause him to fall down. In addition to this, he had pain at the scrobiculis cordis, and the region of the stomach. His urine was scanty and high coloured, and there was pain in passing it. The bowels were confined. It would appear that this disease had sometimes come on very severely, and lasted some time, and then there was a perfect return to ease. Not knowing much better what to do with him, I opened his bowels, and put him upon small doses of colchicum, the same as the other cases.

RHEUMATISM.

A case of rheumatism was also admitted affecting the hands, and which was relieved by warmth.

One of those very bad cases, in which the patient was so frequently ordered to be bled, and according to the treatment which I laid down at the commencement of the course, was put upon guaiacum mixture and a grain of opium at bed time, I am happy to tell you, is going on as well as possible.

The man ALLEN, where the secretion of acid was so great, has entirely recovered. He appeared to me, after the blood-letting, to derive more benefit from guaiacum than any other remedy.

SCARLATINA.

In the case of scarlatina there is a little puffiness about the ankles, showing what would have been the case if we had not bled him, so as to prevent the coming on of anasarca.

PERICARDITIS SUPERVENING ON RHEUMATISM—LARYNGITIS TRACHITIS.

There is a specimen on the table, which has been kindly sent to me by Dr. Macleod, that those gentlemen may have an opportunity of examining it who were not at the autopsy.

This man laboured for some period of his life under rheumatic pericarditis. You may see the old layers of lymph thrown out on the pericardium. He did not die of this disease, but of inflammation of the larynx and trachea. There is extensive inflammation going into the state of ulceration at the upper part of the windpipe. It extends throughout the whole of the bronchial tubes. You may see the notes in Dr. Macleod's book, and compare the symptoms with the present appearances.

ON THE
INDUCTION OF PREMATURE LABOUR IN PREGNANCY
COMPLICATED WITH TUMOR.

To the Editor of the Medical Gazette.

SIR,
I SHALL be obliged by the insertion, in the next number of the GAZETTE, of the accompanying observations.

I am, sir,
Your obedient servant,
SAMUEL ASHWELL, M.D.
Obstetric Lecturer and Physician to
Guy's Hospital.

Nov. 30, 1836.

Mr. Ingleby, the experienced teacher of midwifery in the Birmingham School, has recently published an able and interesting work on Obstetric Medicine. In one part of it there are strictures on a paper of mine, in the second number of the Guy's Hospital Reports, urging the "induction of premature labour in certain cases of pregnancy complicated with tumor;" and against the new principles and practice there recommended, Mr. Ingleby takes large exceptions.

The views contained in that paper are few and simple, and the treatment rests on facts, and is entirely safe. If I did not regard the induction of premature labour as a most valuable addition to our remedial management of these unfortunate complications, I would not occupy your valuable pages by a single word in its defence.

While, however, I thank Mr. Ingleby for the interest he has displayed in the subject, as I am convinced he is in error about it I am bound by my estimation of the importance of the practice to correct misconception, and to shew the general accuracy of the paper.

Pregnancy, whatever may be said to the contrary by Mr. Ingleby, is not unfrequently complicated with malignant tumors of the uterus itself, of the ovary, and with those of a purely adventitious character, growing either from the abdominal or pelvic cavities, and giving rise in labour to difficulties of the worst kind.

It can scarcely be necessary to confirm these statements by extended reference; but I may mention the eighteen cases of Dr. Merriman, numerous others, and my own, as clearly proving the not uncommon coincidence of con-

ception with tumors dangerously obstructing labour. A perusal of Mr. Hewlett's case, in the seventeenth volume of the Medico-Chirurgical Transactions, of several of Dr. Merriman, and of my own (Nos. 1, 2, and 5), will satisfactorily establish the malignancy of the growths themselves. I might enlarge here; but sufficient testimony has been perhaps adduced, to neutralize an opinion of Mr. Ingleby, "that the coincidence of conception with a disease of the uterus, already malignant, is exceedingly rare."

If by the term "already malignant," it be meant that the growths in the unimpregnated state are fibrous, indolent, and harmless, and that their subsequently developed malignancy is the result of the vascular and nervous excitement of pregnancy, then a stronger confirmation of the correctness of my pathology of these enlargements could not be obtained; and if such be Mr. Ingleby's opinion, he must acquiesce in the propriety and advantage of an early termination of the gravid state, as its continuance must induce increased and almost permanent morbid activity of the diseased growths.

Again, Mr. Ingleby "having doubted the accuracy of my views," (a point, I trust, which my present communication may solve,) "thinks it questionable whether the instances already adduced, viz. those of Dr. Merriman, Mr. Hewlett, numerous others, and my own, afford sufficient data to establish, as a general principle, the adoption of the new measure in similar cases."

Now it must be remembered, that I propose to evade the dangers of inflammation of the pelvic tissues and peritoneum, and of the still more hazardous evils of unhealthy softening, suppuration, and ulceration, of the tumors themselves, by the simple and safe expedient of premature labour,—a practice accidentally suggested to me, and enforced on reflection, by the fact that death had frequently occurred where pregnancy was so complicated, under the best known treatment, exclusively of premature labour artificially induced. Nine out of the eighteen cases which fell under the notice of Dr. Merriman, terminated fatally; Mr. Hewlett's case was equally unsuccessful; and three of my own patients fell victims to gangrenous inflammation of the tumors,

produced by their contusion during the parturient process. Worse results could not have followed premature labour; and I feel confident that, had it been induced, several lives would have been saved. Mr. Ingleby would inquire, whether there was not sufficient mischief done to the uterus in these cases to insure a fatal event? Certainly not: in most of the cases mentioned by Dr. Meriman there is no allusion to the condition of this viscus; and when there is, it is stated, with one exception only, to have been healthy. In Mr. Hewlett's and my own examples, the womb was free from inflammation. I believe these patients to have been destroyed, as others will be, where premature labour is not practised, by morbid and malignant changes in the tumors themselves: collapse and final sinking having been induced, much in the same way as after pressure and strangulation of an intestine, or after contusion of the soft parts in difficult labour, where an inspection after death commonly brings into view intense inflammation, and sometimes gangrene and disintegration.

A valuable corroboration of the pathology of the practice, is furnished by the marked success attendant on puncturing the tumors, especially where their contents were fluid, or considerably viscid; and in one or two instances, where blood only escaped. By this operation the bulk and tension of the tumor is diminished, and the double purpose is accomplished of a partial removal of the obstacle hindering parturition, as well as a preservation of the growth from that severe pressure and contusion which may lead to rupture of its parietes, inflammation or gangrene of its substance.

The six cases published by Mr. Park, of Liverpool, in the second volume of the *Medico-Chirurgical Transactions*, are equally in point. Puncturing the tumors was the most successful of all the measures adopted, and it is worthy of observation, that the only fatal termination occurred in a case where the tumor, occupying the recto-vaginal septum, was subjected to the pressure and contusion of the foetal cranium for three days. Delivery was eventually accomplished by the natural efforts, and the patient died in twenty-four hours, from vomiting and constipation.

A perusal of all that has hitherto been written on the subject, will satisfy any

one that the procedure to be adopted in these unfortunate complications, at the time of labour, is by no means clearly defined. If the opposing growth can be pushed above the brim, the parturient difficulty is at an end; but if it cannot be so raised, although puncture of the morbid structure is the best remedy for tumors with fluid contents, it will avail little in the management of solid and very hard growths. Extirpation by the knife may be thought of, but the connexions of the tumor, the shock of the operation, the probable hæmorrhage, and the subsequent inflammation, are events too certain and too hazardous to allow of a favourable prognosis.

These remarks are strictly applicable to morbid enlargements opposing the descent of the child; but they are equally pertinent to hard and malignant tumors of the uterus itself, and to ovarian and other growths, of such magnitude and firmness of attachment as to preclude the possibility (vide Mr. Hewlett's and my own cases) of their being lodged in the abdominal and pelvic cavities, together with the gravid womb, without excitement, pressure, and contusion. This observation is especially true where pregnancy is complicated with one or more hard tumors imbedded in the uterine parietes. If the induction of premature labour were dangerous to the mother—if it increased her risk at the time, or if afterwards it placed her in a worse position than she had previously occupied — Mr. Ingleby's sentiments would carry great weight. It is, however, satisfactory to know that none of these evils are the effect of premature labour artificially induced. Dr. Hamilton, of Edinburgh, my friend Dr. F. H. Ramsbotham, and many others, have frequently resorted to the practice, without the slightest bad consequence. My own testimony, from a rather large number of cases, is equally favourable.

I think, therefore, I may regard as proved, that great advantage will accrue from this method, where the tumor cannot be raised above the brim—where it is situated in the abdomen, and is of such size as to restrain the development of the uterus without painful pressure and contusion, or when the growths are in the uterus itself.

Mr. Ingleby, at the end of his candid and intelligent critique, admits "that an emergency may arise, justifying the measure; but, again, he doubts whether

Dr. Ashwell has sufficiently restricted and defined the principle which he advocates."

I am pleased that Mr. Ingleby, in his five divisions of appended cautions and conditions, has included all and nothing more than what my own paper contains. To this part of my essay I beg the attention of your readers, as this paper is too long to permit their being annexed to it.

OBSERVATIONS

ON THE

FUNCTIONS OF THE MUSCLES AND NERVES OF THE EYE-BALL.

BY EDWARD F. LONSDALE,

Demonstrator of Anatomy at the Middlesex Hospital School.

IN the number of the *MEDICAL GAZETTE* for September the 24th, will be found a paper from Mr. Walker, of Manchester, on the Functions of the Muscles of the Eye-Ball, in which he offers a very ingenious explanation of the action of the superior oblique, by making it act in combination with the external rectus of the opposite eye, by which the parallel motion between the two eyes is produced, when we view any object laterally. It is for this reason, he says, that these two muscles have two distinct nerves distributed to them, while the other muscles have one common to them all.

As soon as I had read Mr. Walker's paper, I was anxious to know how far his theory was probable, and to what extent it was borne out by the anatomy and physiology of the muscles to which he refers the above action, and upon which he founds his theory. I have since considered the reasons he has advanced, and have thought a good deal upon the subject, without being able to come to the same conclusion that he has; for it appears to me, that so far from the superior oblique muscle acting with the external rectus of the opposite eye, that it never acts at all with it, but that its function is quite distinct and opposed to that of the external rectus. I shall give my reasons for supposing this to be the case, presently, after I have stated some of the objections that occur to me with regard to the view he

has advanced; I shall then make a few remarks upon these muscles and nerves generally, and offer what appears to me a likely explanation of the complexity that exists in their mode of distribution and in their function.

Mr. Walker's explanation does not appear satisfactory to me, for, in the first place, I do not consider that the action of the superior oblique of the one eye can be in accordance with the external rectus of the other (even allowing the former muscle to turn the eye inwards); for the external rectus, acting alone, can pull the eye in one direction only, which is horizontally outwards, while the superior oblique rotates the eye upon its axis; and supposing it to turn it inwards, must at the same time turn it downwards: so that the axes of the two eyes cannot correspond if these two muscles act together, for the one will be turned on its vertical axis, and the other on its horizontal. At first sight, then, this view of their action must appear incorrect.

Mr. Walker also states, that it is on account of this lateral motion of the two eyes in one direction, that we find this complexity of the muscles and nerves distributed to them; and that if it had not existed, there would have been no necessity for any muscles except those that are used in looking straight forward. In making this statement, he appears to have quite overlooked the action of the eye-ball in connexion with the motions of the eye-lids, and the many involuntary motions the eyes perform totally independent of this lateral direction, and which renders the existence of many of these muscles necessary, even if this lateral motion had not to be performed. Again: if the use of the superior oblique be only to bring the eye of one side inwards, while the external rectus of the opposite side turns the other eye outwards, how is it that we find this muscle existing in those animals whose eyes are placed laterally, and in whom the parallel motion similar to that in man can never be produced. Take the horse or the sheep, for instance, and suppose that the superior oblique, according to Mr. Walker's theory, were to act with the external rectus of the opposite eye, one eye would be turned directly inwards towards the nose, while the other would be turned outwards towards the ear; so that the animal would be looking for-

wards with one eye, and backwards with the other, producing any thing but a parallel motion between the two. This muscle in these animals, then, and in all others with the eyes similarly placed, must have some other office than that Mr. Walker ascribes to it.

There is another point also in which I cannot agree with him, namely, as to the anatomy and individual action of the superior oblique muscle; for he says that it is "not inserted behind, but directly over, the centre of the eye-ball, or perhaps rather anterior to it, just over the tendinous expansion of the superior rectus, and passing down a little towards the tendon of the external rectus." This statement certainly made me anxious to examine this point again, and I procured a human eye at the earliest opportunity, and have since examined three others, and was much surprised to find the description he gives so different from what appears to me to be the true insertion of the muscle, for I could distinctly trace the tendon of the muscle going quite to the posterior and outer part of the sclerotic, to within about three lines of the entrance of the optic nerve: so distinctly can these fibres be traced, and also seen, when the tendon is pulled upon, that it appears to me difficult to mistake them. They are also made more evident by macerating the eye for a short time, when the tendon can easily be raised up from the sclerotic as far back as its point of insertion.

Such being the insertion of the muscle, its action must be that of rotating the ball of the eye downwards and outwards; for as the point of insertion is brought nearer to the pulley through which the muscle plays, it is drawn in a line upwards, forwards, and inwards, and so must turn the eye in the opposite direction, which is downwards and outwards. That such is the action of the muscle, I have repeatedly satisfied myself on the dead body; and the best way to get the action of it is by first turning the eye upwards as far as it will go, and then pulling upon the superior oblique, when it will be distinctly seen to move in the direction I have stated. This direction outwards, however, is not to that extent to make it an important action of the muscle, but is quite enough to show that the eye is turned contrary to the direction inwards. I believe that the chief action

of this muscle is that of turning the eye downwards and drawing it forwards.

With regard to the nerves distributed to these muscles, Mr. Walker accounts for the fourth and sixth nerves each going to separate muscles, by supposing the superior oblique and external rectus to act together in the lateral motion of the two eyes. Allowing this theory of his to be correct as to the action of these muscles, this explanation of the nerves might appear satisfactory; but if it is found that they cannot act together in the manner stated (and the reasons for supposing they cannot I have given), some other explanation of their peculiar distribution must be sought for.

In speaking of the third nerve, Mr. Walker says, "Now, with regard to the muscles of the third pair, we perceive that they are brought into action in all those motions in which the two eyes correspond, such as straight forwards, with its modifications upwards, downwards, and inwards." Is it meant by this statement that the muscles supplied by this third nerve have the power of acting without the superior oblique and external rectus?—because if so, I conceive that many of them will produce any thing but corresponding motions between the two eyes, namely, the two internal recti and the two inferior oblique; their action together cannot do otherwise than turn the axes of the eyes in opposite directions. From Mr. Walker's statement, I should suppose him to think that the superior oblique and external rectus only act in accordance with one another, and with no other muscles, so giving them a distinct function, having the office only of producing the parallel lateral motion between the two eyes; for he says in the passage I have already referred to, "Doubtless, had it not been for this lateral motion of the eyes, there would have been no necessity for any muscles except those which are used in looking straight forwards."

Another important point which he appears to have overlooked is, that by allowing the superior oblique to turn the eye inwards, and to be the muscle that acts with the external rectus of the opposite eye, the internal rectus is rendered useless; for if this latter muscle is not called into action when the external one of the opposite eye acts, when is it called into action?—for it certainly is not with the internal rectus of the oppo-

site eye, otherwise we should be continually squinting, by having both eyes drawn inwards towards the nose. Where is the difficulty in supposing that, while the external rectus of one eye acts, the internal rectus of the other eye should be brought into action with it, and that the other internal and external rectus should remain relaxed until the eyes are wanted to be turned in the opposite direction? That this action can take place, I shall endeavour to show, and that it is dependent upon a peculiar sympathy between the two eyes, which is essential for the preservation of the parallel motion that must exist, in order to give us distinct and single vision of objects.

Having made these objections to Mr. Walker's theory, I shall now offer what appears to me a more probable explanation of the function of these nerves and muscles, and shall endeavour to show that they admit of being classified according to the peculiar motions the two eyes have to perform, and that their complexity may be much diminished by attending more to the sympathetic action that exists between them than hitherto has been done.

I shall first make a few remarks upon the many different directions in which the eyes can be turned, and mention certain laws that appear to be constant with regard to the action of the muscles connected with them; for it is upon the different motions they are capable of producing, and by attending to those that are voluntary, and those that are involuntary, that their true classification depends.

There appears to be a peculiar sympathy between the two eyes that causes one to follow the other in whatever direction we turn them, and over which we have no command, for we cannot prevent it, however much we try; when we turn one eye, the other must turn too. It is upon this law that our distinct and single vision depends; for, had the motion of both eyes at once been voluntary, we should then have been obliged to be constantly thinking of keeping them parallel to one another while looking at any object; and the least deviation of the axis of one eye from the other would produce indistinctness of vision, and so become an evil of frequent occurrence, by abstracting our thoughts from the object we are looking at.

There is also a sympathy between the

motions of the eye-ball and the eye-lids, for we cannot move the one without moving the other also: thus if we raise the upper eye-lid, the eye-ball follows with it; if we close the eye-lid, the eye rolls upwards, and when we open them again it rolls downwards, so that certain muscles are brought into action quite independent of the will; for we cannot prevent the eye taking these directions, with the above motions of the eye-lids, however much we try.

With regard to the particular action of each muscle, I think it will be found that the following statement is a correct one. When one rectus of either eye acts, the eye-ball will be drawn in the direction of the side on which the muscle is inserted; thus if the superior rectus acts, the eye will be turned upwards; if the inferior, it will be turned downwards, and so on with the other two. If the four recti act together, the eye-ball will of course become fixed, as one will then antagonize the other, and this, no doubt, is one great use of these muscles—namely, to steady the eyes in any particular direction we may require, while looking at an object. It is said that when two of the recti act together, the eye is turned in a direction midway between the two muscles: thus if the external rectus act with the inferior, the eye will be drawn downwards and outwards at once by their combined action.

I am not at all certain, however, that two of the recti muscles ever do act in this manner, so as to pull the eye in an oblique direction; and this is an important point to ascertain, as upon it depends the possibility of the eye-ball being capable of rolling upon its antero-posterior axis, which motion I am inclined to think it never performs; for I believe it will be found that the only action the recti muscles have, is that of turning the eye directly upwards or downwards, inwards or outwards, and that they never act two together simultaneously in the same eye. The following experiment may be made to prove this:—Watch carefully the eye of another person when looking straight forwards, and then tell him to turn the eye upwards and outwards, and to try and carry it in a line midway between the two directions, without either turning it directly upwards or outwards. It will be found that if he perform this motion slowly, he has not the power of doing so; but that the eye is first of all

turned upwards by the superior rectus, and then turned outwards by the external rectus, and so brought to the object wished to be looked at. When the motion is performed quickly, the eye appears to move in the direction at once, for the action of the one muscle follows the other so rapidly, that it seems to take place simultaneously.

If two of the recti, then, cannot act together, so as to bring the eye in a line midway between the two muscles, we should not expect it to have the power of rotating, for, of course, if the eye cannot be brought into the intermediate position, it cannot be brought round from one muscle to another, which motion must take place before rotation can be produced. An experiment may be made to prove this also. If we watch the eyes of another person, and tell him to try and rotate them as much as he can, it will be found that no rotation takes place, but that the eyes are turned rapidly upwards and downwards, inwards and outwards, and that they are never brought into the intermediate position between any two of these directions. Lastly, when we look at the position of the four recti muscles, and at their mode of insertion into the sclerotic, they appear to be more fitted for acting all at once, and so to steady the eye, or else that one alone should act, and pull the eye in the direction of the side to which it is attached.

The fact is, that no rotatory motion of the eyes is required; for when we want to look at any object obliquely, upwards or downwards, we turn the head at an angle that enables us still to move the eyes horizontally; for we can place the head in any direction we like, and so bring the eyes in a position that allows them to turn upon their axis, the same as when looking at an object straight before us.

This lateral motion of the eyes, then, from side to side, being one of the two motions that is most frequently required, and there being also that peculiar sympathy between the two eyes that we cannot move one without the other one following in the same direction, are circumstances that render it necessary that we should have the power over one muscle only; for we only want a muscle to move the eye of the side on which the object we wish to look at is placed; and the other eye must follow by a sympathetic or involuntary power

placed in it, and this one muscle is the external rectus; and now we see the reason why it should have a separate nerve, for in it is the only muscle over which it is necessary that we should have a voluntary power, when looking at objects placed laterally. Thus if we want to look at an object placed to the right, we will to turn the right eye, and the other follows immediately with it (for we cannot prevent it) so that we only want the power over one muscle, which is the right external rectus, and we will to move this muscle, and so turn the eye to the right, and the left eye follows sympathetically. If we wish to look at an object to the left, we relax the right external rectus, and will to move the left, and so turn the eye to the left side, and the right eye follows involuntarily. We have also the power over both external recti at once, which power we employ when looking at objects straight before us; for we then neither wish to move the eye to the right or left, and so make one external rectus act against the other, and the eye becomes fixed directly forwards.

If the above be the true explanation of this lateral motion of the two eyes, there can be no doubt about the external rectus being a voluntary muscle. It now remains to be seen what is the action of the other muscles, and in what manner they are influenced by the nerves going to them. The remaining muscles are the levator palpebræ, the superior, inferior, and internal recti, and the superior and inferior oblique; one of these, namely, the superior oblique, is supplied by the fourth nerve, while the other five are supplied by the third nerve. With regard to the third nerve, it is found to divide into two branches just before it enters the orbit, which two branches remain quite distinct ever after. The superior branch crosses the optic nerve, and supplies two muscles only, namely, the levator palpebræ and superior rectus, while the inferior branch goes below the optic nerve, and supplies the internal and inferior recti, and the inferior oblique. This inferior branch is also further distinguished from the superior, by going to form the lenticular ganglion with the nasal branch of the fifth pair.

It is upon this division of the third nerve into its two branches that I mean to explain the action of the remaining muscles, and wish to show that the

inferior or ganglionic portion governs the involuntary or sympathetic motions of the eye-ball, while the superior or ganglionless portion governs the voluntary motions. In order to support this theory that I have advanced, we must see if these two sets of muscles are so employed, and ascertain if the inferior rectus, internal rectus, and inferior oblique, are used involuntarily or sympathetically, and if the levator palpebræ and superior rectus are used as voluntary muscles.

The muscles the superior division of the third nerve supplies, as already stated, are the superior rectus and levator palpebræ; and there can be no doubt that their action is quite voluntary, for we can will to turn the eye-ball and eye-lid upwards whenever we like; and these two motions are done together, as both muscles are supplied by the same branch of the nerve; and they are required to be moved always in the same relation to one another, otherwise, if we turned the eye-ball upwards without the eye-lid going with it, this motion of the eye would be of no service to us, for we should move the cornea behind the lid, and consequently obstruct our vision by this movement. It was necessary, then, to combine the action of these two muscles together, and to give the voluntary stimulus to both at once, in order to preserve their relation one to another. And this is done by the superior or ganglionless division of the third pair of nerves, which I therefore call the voluntary portion. It now remains to be seen if the muscles supplied by the inferior or ganglionic branch of the third nerve possess the power of acting sympathetically or involuntarily. The internal rectus, one of the muscles supplied by it, I have already shewn to be completely involuntary; for it is brought into action with the external rectus of the opposite eye, and turns the eye inwards, quite independent of the will, for no effort on our part can prevent it following; for while we have a voluntary power over the external rectus, we have none over the internal; it is, therefore, an involuntary muscle.

With regard to the inferior rectus, I think it will be also found to act sympathetically; for it is brought into action only when the upper eye-lid is relaxed, and it appears to have a sympathy with the levator palpebræ; for so long as this muscle acts and keeps the

eye-lid raised, so long are we prevented looking downwards, which we should not expect to be the case were the inferior rectus a purely voluntary muscle. When we want to look downwards, we must first of all relax the upper eye-lid, when the inferior rectus then acts in combination with a portion of the orbicularis palpebrarum, so causing it to be purely sympathetic in its action, for it cannot act independently by itself.

The other muscle supplied by this inferior portion of the third nerve is the inferior oblique; and there can be no doubt about it being purely involuntary or sympathetic in its action, for it turns the eye upwards when the eyelids are closed during sleep, or winking, which motion is quite independent of the will, for we cannot prevent it taking place, any more than we can prevent the eye rolling downwards when we open the eyelids. It is also sympathetic in its action; for we cannot bring the orbicularis palpebrarum into action without the inferior oblique acting at the same time, and producing the involuntary rolling of the eye upwards; in which position it remains as long as the eyelids are closed. So soon as the orbicularis muscle becomes relaxed, the inferior oblique does, but not till then.

The only muscle remaining to be accounted for is the superior oblique; and it, no doubt, is also quite involuntary in its action, for it is the antagonist to the inferior oblique, and not the inferior oblique that is the antagonist to it, as is generally described; for when the eyelids are closed, as during sleep or winking, the eye-ball, as stated above, is rolled upwards, which motion must take place before the superior oblique muscle can be called into action.

When the eyelids are closed, the eye-ball not only is turned upwards, but recedes to a certain extent into the orbit, by the pressure of the eyelids upon its anterior surface; so that it not only has to be rolled downwards, but also has to be brought forwards, when the lids are opened again; and this I conceive to be the office of the superior oblique muscle, for its position and peculiar course fit it for both these motions; its tendon going so far back, will bring the whole globe of the eye forwards at the same time that it rolls it downwards. It cannot be the inferior rectus that rolls the eye downwards during this motion of opening the eyelids, for I have

shown that it cannot act except when the levator palpebrae is relaxed, which of course it is not while the lids are being opened, for then that muscle is in strong action. The only muscle that can do it, then, is the superior oblique, and there can be no doubt about its action being involuntary, for, as before stated, we cannot prevent the eye-ball rolling downwards when the eyelids are opened, any more than we can prevent it rolling upwards when they are closed.

Thus it is seen that there are three voluntary muscles—namely, the levator palpebrae, superior rectus, and external rectus; and two voluntary nerves—namely, the superior division of the third and the sixth; while there are five involuntary muscles, none of which act except in sympathy with the voluntary muscles, and are supplied by two nerves—namely, the inferior division of the third and the fourth nerve.

It may be asked, if the superior oblique be an involuntary muscle, why should it not also be supplied by the same portion of the third nerve as the other muscles that I have called involuntary? The reason I should offer is, that its situation renders it necessary for it to have a separate nerve, as it is far distant from the inferior portion of the third nerve. Also the peculiarity of the course and action of the muscle would lead us to expect a separate nerve to be distributed to it; at the same time that it is also an antagonist to one of the muscles supplied by this portion, the third—namely, the inferior oblique; which is an additional reason why it should not be supplied by the same nerve, but rather have a separate one to itself.

There is a motion of the eyes that I have not yet considered, and one that I think further illustrates the theory I have advanced; I mean where both eyes are turned inwards towards the nose, when we look at any object placed very near. It will be found that if we place the finger, or any object, midway between both eyes, and look stedfastly at it, and then gradually approach it nearer and nearer, both eyes turn directly inwards, and an involuntary squint is produced. The reason of this, no doubt, is, that both external recti becoming relaxed, which they must before the axes of the eyes can suit themselves to an object placed so near, causes the involuntary muscles to come into play,

which are the two internal recti, and they then draw both the eyes inwards, and produce the squint that is found to take place. That the external recti are relaxed in this case, is proved by our being able suddenly to bring them into action, when immediately the near object we were looking at becomes indistinct, and the axis of the eyes is accommodated to an object more remotely placed. We have only again to relax the external recti, and the involuntary squint is immediately reproduced; and we see the object placed near the nose as distinctly as before.

It may be said, that if the above motion of the eyes is dependent upon the involuntary action of the internal recti, how is it that some people have the power of voluntarily squinting inwards? To this I should answer, that it is not found that every body can produce this voluntary squinting; which we should expect they could, were these muscles under the influence of the will; for it is found that some people can only squint in a very slight degree, while others cannot at all. This circumstance I should explain by supposing that some have the power of relaxing both external recti at once, either naturally or from habit, while others have not this power; and as the external recti cannot act until these muscles are relaxed, is the reason why some can voluntarily squint while others cannot.

Squinting downwards and inwards is produced by the voluntary portion of the third also being relaxed, for so long as the stimulus of the will is given to the levator palpebrae and superior rectus (supplied by this upper portion of the third), so long is squinting inwards only produced; but immediately on relaxing these muscles, the eyelid falls, and the inferior rectus then pulls the eye downwards; which it cannot do so long as the levator palpebrae and superior rectus are in action. This motion, then, suits the theory that I have advanced, of the levator palpebrae, superior and external recti muscles, being purely voluntary; for while they are kept in action the eyes are neither turned inwards nor downwards, but immediately on relaxing them they are rolled in both these directions, and an involuntary squint is produced.

This, then, is the explanation I should offer of the action of these muscles, and of the function of the nerves

distributed to them; which I fear, however, may seem complicated, and that many may have objections to advance against them. I merely offer it as one that appears to me plausible, from the fact of its classifying the different muscles in a manner that agrees with their peculiar action, and with the peculiar distribution of the nerves that supply them. The view that I have taken of the superior division of the third nerve being the voluntary portion, and the inferior the portion that governs the sympathetic movements of the eyes, I am not aware to have been advanced before; and it appears to me to be probable, since what I have called the voluntary portion certainly supplies two muscles, over which we have perfect command — namely, the levator palpebræ and superior rectus; while the inferior portion supplies muscles that chiefly sympathize with those muscles that I have called voluntary, and never act by themselves until these latter muscles are relaxed; and this sympathetic action is gained by the peculiar connexion of the inferior division of the third nerve with the lenticular ganglion and the fifth nerve, which is known to give sensation to the eye, and to be the nerve that excites many of the involuntary motions that exist between the eyeball and eyelids*; which motions are produced by this lower division of the third, and by the fourth nerve.

There is another action, also, which goes to prove this lower portion of the third nerve to be involuntary — namely, the action of the iris; which is found to be influenced by it, from experiments that have been made†, and which motion we know to be sympathetic only, and to be dependent on the impressions made upon the retina, and not upon any voluntary stimulus that we can give the iris itself.

I have not mentioned any of the theories that have already been advanced with regard to the action of these muscles, as it would extend my paper to a length that I am not desirous of doing; and they none of them affect the present views that I have put forth. My only wish is to endeavour to do away with some of the difficulties that exist with regard to the physiology of

these parts, by offering what appears to me a simple explanation of the distribution of these nerves, by classifying the muscles according to their peculiar actions, and distinguishing between those which are sympathetic and those which are purely voluntary.

Bedford-Square, Dec. 6, 1836.

CASES OF LOCAL HYSTERICAL AFFECTIONS.

To the Editor of the Medical Gazette.

SIR,

IN perusing the excellent lectures of Sir B. Brodie, on Local Hysterical Affections, published recently in your valuable journal, my mind was forcibly impressed with the importance and correctness of that part wherein he alludes to the mistaken practice of referring the symptoms of hysteria to disease of the spine, and observes, that "in consequence of this unfortunate impression, numerous instances have occurred of young ladies being condemned to the horizontal posture, and even to the torture of caustic issues and setons, for several successive years, in whom air and exercise, and cheerful occupations, would probably have produced a cure in the course of a few months."

From among several cases which have come under my observation, which fully corroborate the justness of this remark, I will select two which occurred a few years ago, premising, that at the time of their occurrence I was engaged in an extensive practice in the country, where I had frequently seen the treatment of *condemning young persons to confinement in the horizontal posture*, made, as it were, a *hobby*, or a *fashionable practice*; being had recourse to without due discrimination, or deliberate investigation into the origin and progress of the more prominent symptoms of disorder, to the benefit of few, but to the serious inconvenience and injury of many.

I shall not relate these cases according to the order of time in which they took place, the second having occurred about two years prior to the first, my object being to exhibit the dangerous tendency and absurdity of the practice

* Vide Sir Charles Bell's papers on the Nerves.
† Mayo's Physiology.

in question, and then to display the advantage of an opposite plan of treatment.

CASE I.—M. B., a healthy looking young woman, who had previously enjoyed an almost uninterrupted exemption from illness, and was employed as a dairy-maid at a large farm, where she had been frequently exposed to the vicissitudes of the weather, applied to me in consequence of suffering severely in her back, with inability to move from one place to another. Whilst motionless in bed she was comparatively free from pain, but she felt acutely when endeavouring to sit up, or to turn herself on either side. She referred the complaint to her getting wet through when milking, and continuing afterwards in her damp clothes, at a period when more than ordinary care was required. Considering the case to be an inflammatory affection of the sacro-ischiatic ligaments, partaking of the character of lumbago rheumatica, I had recourse to venesection, and directed her to have leeches applied to the part, and also gave her a saline aperient mixture, with colchicum. She was much improved by this treatment; but her employers, dreading the expense and inconvenience of her continuing with them, especially as she had no relations residing in the neighbourhood, had her removed to the parochial poor-house. The removal brought on a renewal and increase of the symptoms, for which I adopted a similar plan of treatment to that just mentioned, and subsequently employed cupping and blistering as topical remedies, and gave her a mixture composed of the liq. ammon. acetat., misturæ camphoræ, and pulv. ipecac. co. (in the proportion of six grains of the latter to a dose) three times a day. Considerable amendment ensued, and there appeared a probability of her being soon enabled to leave the house, and return again to service. She was, indeed, so far recovered, that I discontinued seeing her oftener than once in two or three days. Calling one morning with the expectation of finding her below, engaged in some light occupation, I was desired to walk up stairs, where I found her in a *horizontal posture* on a mattress; and was informed that some ladies had been to see her, who had sent another medical man, and he had given directions for her continu-

ing in that position for twelve months. As my term for attending at the house was nearly expired, and the practitioner who had given these orders would in a few days become the parochial surgeon for the ensuing year, according to previous arrangement, I made no comment upon the affair in the presence of the patient, but in conversation with the Master of the house, who expressed his regret that I had been treated, as he expressed it, "so unhandsomely." I requested him to inform the parties that they had acted *incorrectly*, in placing the patient under another surgeon, and having the treatment altered, without making me acquainted therewith; and I also added, that the treatment he had adopted would, if continued, prove injurious to the welfare of the patient.

In alluding to the ladies, whom I represented as acting "incorrectly," I had no intention of reflecting upon their conduct in a general way; it was solely concerning what has frequently proved a source of great annoyance to the surgeon, as many of your readers have without doubt experienced—namely, the injudicious interference of recommending a favourite practitioner, or a peculiar or *fashionable* theory, to which some practitioners, from motives of self-interest (and contrary to their better judgment, if they acted honourably and consistently), are not unwilling to accede. As regards the ladies in question, I had many opportunities of witnessing their benevolence and humanity, which merited the highest commendation; but could not consider their knowledge of pathology sufficient to justify the representation of any who disapproved of a plan of treatment they recommended, as guilty of folly or ignorance.

At different times subsequently I inquired respecting the progress of the case, and was informed that the patient did not improve, but appeared to be gradually declining in health. At length, about nine or ten months from her being *condemned to the horizontal posture*, a surgeon from a neighbouring town was requested by the same ladies to see her, who at once declared the plan of treatment which had been adopted was in every respect wrong, observing, that she ought not in the first instance to have been submitted to it, as she did not appear to have had any spinal disease whatever; and that the only remaining

chance for her recovery was an immediate removal to a more airy and cheerful situation, where she could have the advantage of easy or gentle exercise, if able to bear it, with other means for invigorating her debilitated system, which appeared to be sinking under the effects of consumption. This far more correct and rational plan was adopted; but too late. I called upon her after her removal, at her request, and found her hectic, emaciated, and gradually yielding to that fatal disease, phthisis, to which she fell a victim in a few weeks.

CASE II.—It was, as above stated, about two years before the occurrence of the preceding case, that, in corresponding with a young surgeon who had been my pupil, in one of his letters he mentioned several particulars relating to a young lady, whose parents resided in the town in which he was then living as an assistant, in whose welfare he felt a lively interest. She had been labouring for some time under considerable debility, with occasionally severe pain in the inferior dorsal and lumbar vertebræ. Several practitioners had been consulted, and amongst others a celebrated physician in a neighbouring city, and also a surgeon to a county hospital, a man of considerable experience, and of acknowledged and well-merited reputation. By these she had been directed to be confined to the horizontal posture for a period of not less than nine or twelve months. "Knowing your views concerning similar cases," observed my correspondent, "I have to request your giving me your sentiments upon this." In my reply, I advanced my reasons for concluding the opinion was erroneous respecting the local affection, and the treatment recommended. My letter was read to the parents of the young lady, and as they entertained great dread of her being confined for so long a period, I was solicited to take the earliest opportunity of seeing her. In accordance with their request I visited her (at the distance of thirty miles), and, after a deliberate investigation into the general symptoms and local affection, gave, as my decided conviction, the opinion, that there was not any disease existing in the spine, and that the pain and tenderness experienced in that part did not result from any disorganization of the vertebræ, or of the intervertebral

cartilages, but was merely sympathetic, or dependent upon general or constitutional disorder.

The plan of treatment I advised was that of endeavouring to improve the system by tonic medicines, diet of a nutritious or invigorating quality, and gentle exercise in the open air, with the occasional use of the shower-bath and flesh-brush. The season of the year was favourable to recovery, it being early in the summer; and I was gratified by the result; for in the space of two months she was so far recovered as to be able to visit a relation above a mile from the town, walking all the way; and was soon after perfectly restored to health. The subsequent history of this case has been truly satisfactory. My patient has since that period enjoyed good health, with an exemption from the local disorder. She afterwards married the young surgeon, who is now in excellent practice in one of the principal cities in the west of England; and she has become the mother of five fine and healthy children.

I shall forbear an extended comment on these cases, as it is probable similar ones have come before the observation of many of your readers. The first I consider as an exemplification of the evil effect of pertinaciously adhering to mistaken theory, and the second as a happy illustration of the good resulting from a departure from theoretical opinions (as regards any peculiar method or plan of treatment), notwithstanding they may have obtained sufficient public approbation to render them what has been denominated popular or fashionable, or to have been recommended by some of the most eminent members of the profession. Had the first been allowed the use of her limbs, and occasional exercise without fatigue, in all probability she would soon have obtained a restoration to the enjoyment of health; and had the second undergone her nine or twelve months' confinement to the horizontal posture, it is not unreasonable to conjecture that she would not, as she is at present, have become the healthy parent of a fine and healthy progeny.—I am, sir,

Yours very respectfully,

J. F. HULBERT.

RE OF AN OPEN CANCER OF THE BREAST.

the Editor of the Medical Gazette.

SIR,

The number of your journal published the 15th Oct. a very brief account is given of a case of cancer of the mamma, treated last spring in the Glasgow Infirmary with hydriodic acid. Through the kindness of Dr. Craig, High-Street, to whose care the patient now is, I have procured the following history of the case, subsequently to the time of being dismissed as incurable from the Infirmary. I consider myself in a degree bound to publish this history, in consequence of its being in direct opposition to the very unfavourable prognosis recorded in your journal; and Dr. Craig and myself concur in thinking that it will probably not be read without interest by your professional brethren. I extract the original from the Infirmary Journal (see Journal for 1836, Ward No. 8, pp. 131, 132, and 139), and shall add the subsequent history and an account of the present state of the disease.

Janet Herriot, æt. 40, married. Calcutta, Jan. 21, 1836.—About three years ago she first observed a small tumor, about the size of a common pea, situated at the base of the nipple of left mamma. It gradually increased in size, its growth being accompanied by occasional attacks of lancinating pain. It now occupies about one-half of the gland, being about two inches and a half in diameter. It is hard, and pretty regular in its form, and moves freely on the pectoral muscle. Three weeks ago the skin surrounding the nipple became thickened and ulcerated. Ulceration has spread considerably, sore now measuring about an inch and a half in diameter. The nipple has been absorbed, and surrounding integuments are of a livid colour. Eight days since had a rigor, followed by pain, swelling, and redness along the lower border of the pectoral muscle, and slight enlargement of axillary glands. Since this attack, pain and uneasiness have much increased, and have been accompanied by a degree of feverishness. Health previously good; tongue whitish, somewhat florid

at tip; bowels costive; catamenia regular, and always preceded by increase of pain of breast.

Loco dolenti admoveantur Hirud. x. et postea Cataplasma. Cras m. s. Ol. Ricin. ʒi.

February 13th.—Inflammation of lymphatic glands having been subdued by leeching, and a consultation having sanctioned the removal of tumor, should patient desire it, the day for operation was fixed, but it was not performed, in consequence of a slight attack of erysipelas: redness of surface now gone, but there remained under skin covering pectoral muscle several hard lines, size of whip-cord, and a gland above clavicle is now felt hardened and enlarged.

Sum. ter indies Acid. Hydriodic. Liquid. ʒss.

March 26th.—Has used hydriodic acid since last report. No change in glands of axilla and above clavicle; tumor of mamma larger, and ulceration deeper, more extensive, and very foul. Little change in pain, though for the last two days it has been aggravated; pulse 84; general health pretty good.

Dismissed, with advice to use hemlock poultice, &c. &c.

November 11th.—The patient now resides in New Vennal, and is better known by the name of Mrs. Williamson. According to the account she gave yesterday to Dr. Craig and myself, for about three months after she left the Infirmary the sore of breast continued to increase in size, and her general health to decline. When the sore was at the largest, it was as broad as the mouth of a tea-cup, and very deep: it had the same foul appearance as when she left the hospital, and yielded a thin dark-coloured discharge, which she compared to moss-water, and which was so profuse as to soak through the dressings, and keep her clothes constantly wet: the fætor was loathsome to herself and all around her. At this period she had an attack of dysentery, which reduced her strength to a very low ebb, and dried up the sore; but on the dysentery subsiding, the discharge returned. About ten weeks ago she was recommended by a friend to apply citrine ointment, and after various unsuccessful attempts to procure what she considered the genuine ointment (for she was particularly warned against a *bastard* kind of it), she succeeded in

procuring from Dr. Craig an ointment with which she was satisfied, and which was the unguent. citrin. dilut. of the Edinburgh Pharmacopœia. On the application of this ointment, the sore began to improve; it was a good deal better when Dr. Craig first saw it, and from that time the filling up and cicatrization of the sore have gone on without interruption. The patient ascribes her cure partly to the ointment and partly to her *good nature*, which she says she was always confident would carry her through.

On examining the breast, the cicatrix left by the sore was found to be about two inches in diameter, indurated, and quite flat. No ulceration could be perceived upon it, but in the centre there was a thin crust, which, according to the patient, consisted of the ointment applied, but which seemed, in part at least, to be formed by an exudation from beneath. The surrounding parts seemed quite healthy. Several of the axillary glands were enlarged; one of them, in particular, was as large as a chesnut, and very hard. No trace of the enlarged lymphatic vessels, or of the gland above the clavicle, could be discovered. No pain or any other uneasiness is felt, either in the breast or the axilla. Her general health is perfectly good; strength quite restored; tongue clean, and pulse natural.

The preceding case is interesting, as establishing that a genuine cancer of the mamma does admit of being cured, to whatever circumstances the cure is to be ascribed. That the disease was really cancer no doubt can be entertained. The period of life at which the tumor occurred, its progress, and, above all, its characters cognizable by sight and touch, were such as could leave no doubt in the mind of any person in the habit of examining such cases, as to the true nature of the disease.

At a full consultation held upon the case, no difference of opinion was expressed as to the nature of the disease; but, as very often happens in the advanced stage of cancer, while one-half of the gentlemen present recommended that the woman should be allowed to die in peace, without being subjected to the pain of an operation, which they thought would only accelerate her fate, the other half considered it right to give to her whatever chance of life excision might hold out.

If any further evidence of the truly cancerous nature of the disease were required, it is unfortunately still to be found in the state of the glands of the axilla, which, I regret to say, have too much of the characters of cancer. That these glands will not hereafter give trouble, and that the woman can be considered as free from all risk of a recurrence of the disease, it would be rash to predict. All that can be said, in the meantime, is, that a cancerous sore of the breast, instead of going on from bad to worse till the destruction of life, after spreading to a certain size began to improve, and ultimately healed, the patient at the same time recovering her health and strength.

With respect to the remedies which were used, the patient took the hydriodic acid internally, and had poultices and citrine ointment applied to the sore. The hydriodic acid was begun soon after the ulceration commenced, and was continued for forty-two days; the quantity of iodine taken being 2460 grains. The iodine appeared as usual in the urine, but never could be detected in the discharge from the breast. The poultices were applied during the early stage of the ulceration, and the citrine ointment was not resorted to till after the sore had spread to its utmost extent. What share these remedies had in the cure which was effected, or whether they had any share in it, cannot be determined by the result of a single case. Farther experience of their effects is therefore required; and while the acknowledged inutility of all other remedies will operate as an inducement to make fresh trials, it cannot fail likewise to cast doubt in the meantime on the probability of their success.—I remain, sir,

Your very obedient servant,
ANDREW BUCHANAN.

Glasgow, 110, St. Vincent-street,
Nov. 12, 1836.

“WHICH ARE THE NERVES OF TASTE?”

—NOT YET DETERMINED.

To the Editor of the Medical Gazette.

SIR,

IN a late number of the *MEDICAL GAZETTE** you have given insertion to a

* Present vol. p. 225.

paper by Dr. Alcock, of Dublin, wherein the author assumes to have determined the question relative to the nervous connexions of the sense of taste. I propose to offer a few remarks upon the inferences which have been deduced from the experiments narrated in this paper, inasmuch as it appears to me that they are by no means warranted by the premises, and that, as some of them are totally at variance with recognised *principles* in physiology, we must look for evidence of a much more decisive character, before Dr. Alcock can be allowed to have determined the question "which are the nerves of taste?"

Dr. Alcock, at the conclusion of his paper, observes—"I feel justified in drawing the following inferences from the experiments and reasonings which have been detailed: 1st, that taste is a special sensation; 2d, that it enjoys two media of perception; 3d, that its media of perception are the glosso-pharyngeal nerves, and the lingual and palatine branches of the fifth nerves; 4th, that the glosso-pharyngeal nerves are not its special media; 5th, that the latter nerves both are sentient, and influence muscular action; and 6th, that the spheno-palatine ganglion and chorda tympani, have no influence upon either the existence or perception of the sense."

With the first of these propositions I shall certainly not find fault; but I deny that it is proved by the experiments of Dr. Alcock. It appears to me that, if we may rely upon the accuracy of his data, "taste" is *not* a special sensation, inasmuch as it is dependent upon no *special* nerve, but associated with two nerves whose main functions, according to Dr. Alcock, are, the one for "muscular action," and the other for "common sensation;" just as if these nerves disposed of a little superfluous endowment to produce the sense of taste. However, that taste is a specific sensation, and not a modification of the common tactile sensibility of the tongue, I consider to be fairly established; I believe the conclusion to be fully warranted by certain cases, with experimental investigations, observed by the present writer, first published in the *MEDICAL GAZETTE*, and afterwards appearing in some of the Continental and American journals. I assume no originality in having long doubted the accuracy of

the popular doctrine that taste was only a modification of common sensation; but, until it shall appear that I have been anticipated in my observations, I must claim priority in having *demonstrated*, by the best kind of evidence, that "taste is a special sensation."

If reference be made to the *MEDICAL GAZETTE* of Oct. 25th, 1834, a paper of mine will be found, wherein the following conclusions are assumed to be warranted, from previously recorded experiments upon a patient labouring under one of the forms of facial paralysis, "that whilst the common sensation of one half of the tongue was annihilated, the sense of taste was unimpaired. Does not the above case decide that taste is something more than a modification of common sensation? And if so, must it not, as in the case of smell, be dependent upon a specific nervous supply?"

In the *GAZETTE* of Nov. 21, 1835, another case of facial paralysis, which I had investigated, was published, and the following remarks occur towards the conclusion of the paper.—"These experiments were considered to render it clear that, in this case, whilst the common sensibility of the left half of the tongue was but little impaired, its specific feeling was lost."

These cases, then, manifesting, in one instance, loss of feeling with maintenance of taste, and, in the other, loss of taste with maintenance of feeling, it will, I think, be generally allowed that the inference which I have always drawn from them is warranted; and I regret that in *assuming* to have determined, amongst other things, that "taste is a special sensation," Dr. Alcock has not had the candour to refer to what had been previously offered to the profession by myself. He may certainly have been unacquainted with the full share which I have had in the discussion of this question, though it is somewhat singular that he should have shewn himself to be well acquainted with some of my *suggestions*, and yet be in ignorance of the *facts* with which those *mere* suggestions have been accompanied.

I remarked at the outset of the present communication, that some of Dr. Alcock's inferences were at variance with principles generally recognized in physiology. The proofs of this may be

demand. Is it not, then, a recognized principle in the physiology of the nervous system, that a simple and special function must have but one simple nerve for its manifestation? and, reciprocally, that a nerve whose origin is simple, can subserve one function only? Let Sir C. Bell, and other leading authorities, decide this point; a reference may readily be made to their works. Well, but Dr. Alcock infers, in the second place, that taste, which he allows to be a *special* nerve, has *two* media of perception; and, thirdly, that these media are the glosso-pharyngeal nerves and certain branches of the fifth pair; and, fourthly, that the glosso-pharyngeal nerves are not its *special* media, though nerves of a special sense; and, fifthly, that the latter nerves (whose simplicity of origin is not questioned) perform two functions—the functions of both motion and specific sensation.

Without proceeding farther, has not enough been said to shew the inconsistency of Dr. Alcock's inferences with some of the best established principles in physiology? But it will be contended, that if *facts* disprove the correctness of such principles, these latter must be modified so as to accord with the facts. Most assuredly; such reasoning is unexceptionable. But the accuracy of the facts themselves must first be established; and that Dr. Alcock's paper furnishes the proofs of such accuracy, most, I conceive, will be inclined to disallow. I do not, however, propose to examine seriatim, and in the detail, the various proceedings which were adopted in this gentleman's experiments; but I protest altogether, and in the wholesale, against the possibility of coming to certain conclusions, upon such a subject, by mutilation of living animals. So far as such experiments could be considered to have proved any thing, those of Panizza demonstrated that the glosso-pharyngeal was the nerve of taste, to which conclusion no argument from analogy could be opposed; but shortly after the publication of their performance they were repeated by Mayo, and with contrary results. And again, Dr. Alcock's experiments would prove Panizza and Mayo alike to be both right and both wrong. I must reiterate, the whole procedure, as a means of "determining" the question, is, in my own

humble judgment, unsound and fallacious.

It is to pathology, and to morbid anatomy, that I look for the ultimate settlement of this matter. Pathology, I consider, has proved that taste is a *special* sense, and I expect that morbid anatomy will hereafter reveal its *special* nerve.

I am, sir,
Your obedient servant,
DANIEL NOBLE.

Manchester, Nov. 29, 1836.

PREPARATION OF BROMIDE OF IRON.

To the Editor of the Medical Gazette.

SIR,

I HARDLY know whether I am correct in troubling you with the following reply to Mr. Squire's note, in the GAZETTE for last week; indeed, the relative merits of the bromide and iodide of iron are not of sufficient interest to justify any lengthened consideration of the matter in a periodical which has always subjects of vastly higher importance to introduce to its readers.

The decomposition of the bromide of iron will be exactly proportionate to the purity of the preparation, and this will depend mainly on two circumstances—the state of the iron which is made use of, and the accuracy of the manipulation.

With reference to the first, I beg to remark that the use of iron filings is extremely objectionable, even when separated by the magnet; not that I can suppose that a wholesale drug-vender would even make use of this simple artifice to produce a pure article. To obviate any chance of impurity from the iron, I have directed fine iron wire, in the form of a coil, to be used.

There is also an important point to be observed in the manipulation. In evaporating the solution, a very gentle heat must be used, or the bromine will be separated in the form of gas.

It is to a preparation made with these precautions that I alluded when I stated that it could be kept in a state of solution for weeks, without any appreciable decomposition taking place. I had made a series of careful experiments before I presumed to send you my paper,

some of them verified by repetition, under very unfavourable circumstances; and as to any attempt on the credulity of your readers, no man, with any claim to sanity, would, with such an object, have communicated his name and address.

A coil of wire will certainly render the solution of the iodide less liable to decomposition, but a coil of wire cannot be sent in a mixture to a patient. The solution of the bromide needs no such precaution, if *originally well prepared*.

I must again apologize for even giving you the trouble of reading this; in fact it is a matter of perfect indifference to me, whether the iodide or bromide be preferred. I had observed certain advantages occur during the administration of a therapeutical agent, and having good reason to suppose that the benefit and medicinal preparation stood in the relation of cause and effect, I felt justified in recording the same, with the hope that publicity would elicit truth.—I have the honour of subscribing myself, sir,

Yours very respectfully,
GEORGE KEMP.

Cheshunt, December 6, 1836.

P.S.—Mr. S. speaks of the coil of wire keeping the solution in a *neutral state*; the fact is, that what, for brevity, I have called a *bromide of iron*, is a *per-bromide*.

EXTRAORDINARY
ACCUMULATION OF FÆCES
IN THE
LOWER PART OF THE RECTUM.

By JAMES HEYGATE, M.D.
M.B.C.S. London, and Physician to the Derbyshire General Infirmary.

AN occurrence of the following nature, at least to the extent mentioned, does not frequently happen, and when it does it must be attributed to neglect. The only practical advantage to be gleaned from its recital, is to put physicians on their guard should a like occurrence befall them. Much distress is often experienced by elderly bedridden patients from a similar, though lesser evil, of this sort; many of whom are not able to describe their own feelings. Whenever,

therefore, they suffer from obstinate constipation, and where the administration of active aperients only increases the distress, it is most important to ascertain the state of the rectum, and see whether some insuperable barrier, in the shape of hardened fæces, do not present itself. The ineffectual attempt of the nurse to introduce an enema pipe has frequently been the first indication of such a cause.

Mrs. S. between 60 and 70 years of age, (who had been for some time previously bedridden) told me that for some days she had suffered most excruciating pains in the lower part of the rectum, which came on at tolerably regular intervals, assuming precisely the character of the pains of parturition. I questioned her as to the state of her bowels, and she told me that they were quite open, and that frequently some loose evacuation came away; this led me to suppose that the pains might be produced by some peculiar irritation, or ulceration, &c. As she was very reluctant to be examined, I prescribed some medicine calculated to relieve pain. I was however summoned early the next morning, and told by the daughter that her mother had had a most dreadful night, with "the forcing down pains." Having now acceded to an examination, I immediately found that an immense hard, dry ball of fæces, was making fruitless though strong attempts to pass the anus, which was greatly dilated; so much so, as to be compared to nothing better than the os uteri, when pressed upon by the caput of the descending fœtus, and dilated to the size of a crown piece or more.

Mrs. S. being very thin, and the surrounding parts greatly attenuated by pressure, I could with my fingers distinctly trace the size of this hard ball, the form and circumference of which, was, without exaggeration, similar to the head of a full-grown fœtus.

Notwithstanding her exhausted state, nature had made most extraordinary efforts to dilate the anus sufficiently to pass this hard ball of clay, which it resembled both in colour and consistency. After ascertaining as nearly as possible the extent of the accumulation, I with the handle of a tea-spoon (having no better instrument at hand) with some difficulty broke down the mass and brought it away piece-meal, and then ordered an enema to be administered,

which effectually removed the remainder. Strict injunctions were enforced, calculated to prevent a recurrence of this evil.

I ought to have said, that on examination, some loose feculent matter was found to pass with the pains—it escaped round the sides of the ball. This apparent action of the bowels prevented, in the first instance, all suspicion of the cause of the ailment, and deceived both the patient and myself.

Derby, Nov. 10, 1836.

THE
METHOD OF OBSERVING
THE
TUBULO-FIBROUS STRUCTURE
OF THE BRAIN.

To the Editor of the Medical Gazette.

SIR,

THE admirable discovery of Ehrenberg, of the fibrous structure of the brain, not having been observed in this country, it may be interesting to many of your readers to learn in what manner it may be seen; for even as a microscopic object, a more beautiful and delicate one I have not examined, while, in a physiological point of view, its high importance is evident to all.

The brain which I examined was that of a sheep, which had only been killed about half an hour; it had been immersed in weak spirit, which corrugates it, and should not be used; it must, however, not be allowed to dry.

Exp. 1.—I cut a thin transverse section of the *tractus opticus**, and placed it, with a little water, between two slips of glass, using a slight pressure. When this was placed under the microscope, charged with a power equal to a single lens of one-twentieth of an inch focus, the whole appeared as composed of a granular amorphous mass, surrounded by a thin transparent membrane. On more attentive examination, the particles appeared to me to consist of short broken fibre, but the evidence was not sufficient to come to any positive conclusion; though I felt convinced they were not globular.

* Mr. Lucas kindly furnished me with the brain.

Exp. 2.—I now carefully cut out a small longitudinal piece from the same part of the brain, laid it on a slip of glass with a little water, and covered with a very thin plate of mica; avoiding even the slightest pressure. Under the same amplification the edges appeared irregular, but no fibrous characters could be discovered. I now charged the instrument with a power equal to a single lens of one-fiftieth of an inch focus; using a fine achromatic object glass, with an aperture of 55°. I could now distinctly see fibre (indeed the whole mass appeared composed of it), but I could not decide whether it was tubular; nor was the evidence sufficient to say whether they were of uniform diameter throughout their length. On placing a diaphragm, with a condenser, behind the stage of the engine, to direct the light properly through them (an arrangement always advisable for the examination of cylindrical bodies*), I was enabled, without altering the power, to see the enlargements at certain intervals, and also to determine that the fibre was tubular, as shewn in the figure. The tubes near the edges having separated, their structure was quite evident.

The diameter of the constricted parts, I find, varies from 1-1500th to 1-1800th of an inch.

Hoping the above will be useful in enabling others to verify this valuable discovery, I remain, sir,

Your obedient servant,

ANDREW PRITCHARD.

263, Strand, Dec. 7, 1836.

ACCOUNT OF THE LATE CASE OF
POISONING WITH UNSOUND
BACON.

to the Editor of the Medical Gazette.

SIR,

I leave to correct two mistakes into which the reporter for the *Times* has fallen, in his account of the inquest on the body of Caroline Jones, whose death, many were of opinion, was occasioned by eating diseased or unwholesome bacon, and which report has been transcribed to your columns. The medical witness on the occasion was myself, and in the report he is described as "John Thomas, surgeon to the hospital." Again, in the evidence of Edward Jones, the father of the deceased, a mistake occurs. Instead of "servant had gone out with a younger child," &c., it ought to have been, "the deceased had gone out," &c. The case is one of some interest and importance in a medico-legal point of view, and as the medical history, as given in evidence, was necessarily brief and defective, I take this opportunity of supplying you with a more detailed account of the symptoms and *post-mortem* appearances.

I was gratified to find that the view which you have expressed of the case in our editorial capacity, is the one which seemed most satisfactory to my own mind, although I must observe that, at the dissection, there were some gentlemen—including one of the physicians to the hospital, who regarded the appearance as the result simply of continued indigestion, with severe abdominal complications.

These gentlemen, however, had I believe, watched the progress of the case. On the other hand, it has been stated, and I think not without reason, that the severity of the symptoms was such as to lead to the idea of a mineral, rather than an animal poison; and allusion was particularly made to the possibility of the bacon having been cooked in a dirty copper. At my suggestion, therefore, a particular inquiry was directed to this point at the inquest, but there did not appear to be the least ground for supposing that any mineral poison had been introduced into the meat, either by

carelessness, accident, or design.—I am, sir,

Yours very respectfully,
JOHN THURNAM.

Westminster Hospital,
Dec. 11, 1836.

Caroline Jones, aged 14, was admitted into St. Margaret's Ward, Westminster Hospital, November 8th, as a patient of Dr. Bright. She complained of extreme pain in the epigastric and right hypochondriac regions, which was greatly aggravated by pressure, with almost constant and profuse diarrhoea; some tenesmus; evacuations fluid, watery, and deficient in biliary matter. There was considerable emaciation; countenance generally pale; centre of each cheek flushed; features expressive of intense suffering, being drawn into a sardonic grin. She lay in bed on the right side, with the knees drawn up to the abdomen. Skin rather hot and dry; tongue very dry, covered with a thin brown coating; lips parched, and rough; pulse very frequent, small, and wiry; thirst excessive.

App. Hirud. xx. regioni Hypochond. dext.

R Hydrarg. c. Creta, gr. v. Pulv. Ipecac. Comp. gr. viij. M. ft. pulvis statim sumend.

9th.—R Pulv. Cretæ Co. 3j. Hydrarg. c. Creta, ℥j. Pulv. Ipec. Co. 3ss. M. ft. pulveres, viij. Capt. j. ter quotidie.

This treatment was persisted in, with but very temporary relief; the leeches, in diminished number, being repeated at intervals of from two to seven days. One of the most prominent symptoms at this period was the extreme thirst; the quantity of milk and water, of barley and toast-water, that she consumed, being excessive.

19th.—Rep. Hirud. viij.

R Hydrarg. Submuriat. gr. j. Opii, gr. ʒ. M. ft. Pilul. ter quotidie sumend.

22d.—App. Emp. Canth. Epigast.

A day or two after this a little improvement appeared to be taking place; the pain became less severe, and, indeed, gradually left her, but she still suffered from extreme tenderness. The countenance became less expressive of suffering, and the cheeks less flushed; the tongue was cleaner, and the appetite improved so much that she asked for animal food, and was allowed a mutton-chop. The pulse became fuller, softer,

and less frequent. The diarrhoea still continued, but in a less severe degree.

About the 29th or 30th of November she was rather suddenly taken worse; the pain and tenderness upon pressure returned with increased severity; every symptom was greatly aggravated; slight delirium came on; the countenance was anxious and sunken, the features being occasionally distorted; some strabismus was noticed occasionally. Emaciation made great progress, the powers of life gradually sank, and she died Dec. 2d.

Inspection of the body, 16 hours after death.—Brain healthy. Thoracic viscera free from disease, with the exception of a few crude tubercles dispersed through the lungs, which organs were also rather congested.

Abdomen.—The stomach contained from one to two pints of a rather thick glairy fluid, consisting of coagulated milk, bile, and mucus; its tunics were rather attenuated; the mucous lining soft and grey, having a layer of viscid mucus adherent to it. There was obviously increased vascularity of this organ, chiefly affecting the capillaries and smaller arterial branches of the cul de sac, and greater curvature. The duodenum was considerably dilated, with decided thinning of its parietes; its mucous surface had a regularly mammillated appearance, dependent apparently upon hypertrophy of its mucous follicles; there was also a diffused blush of redness in this membrane. No farther morbid appearances were detected in the small intestine, until approaching within about twelve inches of the cæcum, when irregularly-shaped patches of ulceration were met with in the mucous membrane; these were seated chiefly in the side of the gut, opposite to the attachment of the mesentery, and became larger, and deeper, and more numerous, as the cæcum was approached. Ulcers were also met with in the ascending and transverse portions of the colon, but the remainder of the large intestine, including the rectum, was healthy. One of the ulcers in the ileum, situated in the angle formed by that gut with the cæcum, had produced a perforation of the canal, and this had led to a peritonitis, affecting the serous covering of the lower half of the abdominal viscera, these being covered in many places with flakes of recently-formed false membranes, and about half a pint of sero-albuminous fluid being

present in the pelvic cavity. The mesenteric glands were enlarged, and presented an increased vascularity; upon being cut into, they reminded one most of the character of a fine erectile tissue. The other abdominal viscera did not present any abnormal appearances.

THE LANCET WISEACRES
ON
INCISION OF THE PERINEUM IN
LABOUR.

To the Editor of the Medical Gazette.

SIR,

THAT the Editor of the Lancet is blessed with a due number of dull correspondents the columns of that publication leave us no room to doubt; but we were charitably enough inclined to consider the insertion of Mr. Rolland's letter as a mere oversight, and laughed at the blunder accordingly; for we considered the letter itself a sufficient indication of the state of the writer's mind, nor for a moment imagined that a production in which there is neither a connected sentence nor a sane idea, could have called forth a reply. It appears we were wrong.

The serious refutation of poor Rolland's proposition by two separate correspondents in the Lancet, is too absurd an affair to be altogether passed over in silence. The sombre gravity of the former of these obstetric Quixotes is irresistibly comic; nor is the triumphant self-gratulation of the second less ridiculous. This latter hero informs us, in a note, that in the Army the opportunities of obstetric observation are necessarily rare. What can the man mean?

We recommend the Editor of the Lancet to suppress the names of his future contributors from *Fort Clarence*.

We remain, sir,
Your obedient servants,
TWO OR THREE.

Fort Pitt, Chatham,
Dec. 12, 1836.

[This letter has been duly authenticated. It may be necessary for the information of our readers to add, that Mr. Rolland's, of *Fort Clarence*, suggestion was to divide the perineum at once whenever it offered any obstacle in parturition! Fort Clarence, it is well known, is the place where officers of the Army, who are "under observation," are confined.—*ED. GAZ.*]

PHYSIOLOGY OF SALIVATION.

To the Editor of the Medical Gazette.

SIR,

PERMIT me to offer a few remarks on an article entitled the "Physiology of Salivation," which appeared in your number for Nov. 26, 1836.

The author, in explanation of this phenomenon, proposes a theory which is novel, and somewhat ingenious. It may be briefly stated thus:—The pancreas stimulated to increased action by the internal administration of mercury, pours forth in profusion its peculiar secretion. After a time it falls into a state of atony, and is unable to secrete even its usual quantity. But the full amount of pancreatic fluid is elaborated in the blood. To prevent the ill effects which would arise from its accumulation, the salivary glands, already unusually excited by mercurial stimulation, take on increased action, and pour forth the pancreatic, or some analogous fluid. This is the physiology of salivation.

Of the many objections which might be urged against this theory, it is sufficient to mention two. 1. Salivation may be excited by mercury applied externally, long before the chain of sequences supposed above can be established. 2. The pancreas is regarded by physiologists as analogous in structure and functions with the salivary glands. Admitting, then, that exaltation of the action of an organ is followed by depression, the salivary glands having suffered during salivation from continued excitement, will, after a time, become atonized, and probably the quantity of their secretion will be diminished. But, according to the above theory, the full amount of salivary fluid will be elaborated in the blood. Injurious effects would ensue from its accumulation; it must have egress through some channel. The pancreas, which now will have recovered its tone, seems well adapted for the purpose; it is roused again to increased action; but depression will follow, and the phenomena described above will be repeated. Thus there will be alternate discharges of salivary and pancreatic fluids for ever. This is absurd.

It may be objected to the case I have just proposed—that the pancreas

had suffered no mercurial stimulation antecedent to its increased action. In the above theory it is not stated that such stimulation is the sole or necessary cause of exaltation of function.

It is easy to demolish theories—it is easy, even in the absence of facts, to substitute others in their room. Far be it from me to attempt the solution of a question so difficult as the physiology of salivation—a question which involves the inquiry as to the *modus operandi* of mercury on the human body.

I venture, however, to throw out a conjecture as to its *immediate* cause—a conjecture which appears to me to derive support from the order of supervention of the pathological conditions, and from analogical reasoning, which is just, and apparently conclusive.

The symptoms attendant on a case of salivation may be arranged in three divisions. They are developed in the following order:—

1. "Slight tenderness and tumefaction of the gums, which acquire a pale rose colour, except at the edges surrounding the teeth, where they are deep red. The mouth becomes sore; the tongue swollen.

2. The salivary glands become tender and swollen; the saliva and mucus of the mouth flow abundantly.

3. If the use of mercury be continued, aggravation of the 1st division of the symptoms; the gums slough, the teeth drop out, and there is necrosis of the alveolar processes*."

Distinct conditions are marked out by the first and second division of these symptoms. The 1st division indicates inflammation of the mucous membrane of the mouth; the 2d, inflammation of the salivary glands. It is evident, then, that salivation occurs subsequently to the inflammation of the buccal mucous membrane. Analogy favours the conjecture that this inflammation is its immediate cause.

What doctrine of pathology is more firmly established than this—that inflammation of glandular structures is often excited by irritation of the surface of relation with which they are in contact; for example, the lesion in duodenitis, the mesenteric glands in enteritis, &c. Can we refuse to apply this doc-

* Pereira's Lectures, MEDICAL GAZETTE, vol. xviii., p. 388.

trine to the case in question? The analogy is too powerful to be rejected. Again; stimulants taken into the mouth induce temporary salivation; and finally, Bichat has shewn that stimulation exerted on the surface of relation with which glands communicate, is the natural mode of excitement of these organs.

The conjecture, then, that salivation is a consequence of inflammation of the mucous membrane of the mouth is not unfounded. This, however, advances us but a little way in our inquiry. The question meets us as to the cause of the development of this inflammation. To treat on this subject at length would require more space than I could presume to occupy in your journal.

I remain, sir,

Your obedient servant,
Z.

December 6, 1836.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abrégé."—D'ALEMBERT.

Annales d'Hygiène publique et de Médecine légale. No. XXXII.

THE new number of the *Annales* contains several excellent articles, of some of which we can at present do little more than mention the names.

On *Suicide*, as it prevails at the present period, by M. Brouc, is an elaborate paper, in the composition of which the author has availed himself of extended and varied resources. The next article is M. Ratier's prize essay on the *Best means of arresting the spread of Venereal Disease*. After which we have *Memoirs* by MM. Rengi, Santi, and Kuhlmann, on different subjects of hygiene.

In the department of legal medicine, we have two able papers by M. Ollivier d'Angers and Professor Froriep, of Berlin, on the determination of the question—*What is properly to be considered a new-born Child?*—an inquiry extremely necessary to be made in reference to the French and German criminal codes. In this country a similar question might not improperly be proposed—What, strictly speaking, is *In-*

fanticide?—for, in accordance with legal phraseology, it might imply the murder of any person under the age of one-and-twenty. An interesting medico-legal report on a *Case of supposed Infanticide* is given by M. Schneider, of Fulda, communicated by M. Marc: after which comes a short case of *Supposed Poisoning*—but actual suicide, related by M. Boutigny. We are glad also to find that the Editor begins to look to our English books for material in this department: he has extracted from Mr. Alfred Taylor's "Elements" that gentleman's remarks on the *cause of death by hanging*.

These, together with the *Varieties and Bibliography*, make up a number of considerable value. We shall give a more satisfactory account of some of the contents hereafter.

A Medical Vocabulary; or, Explanation of all names, synonymes, terms and phrases, used in Medicine and Surgery, and the relative branches of Medical Science. By a MEDICAL PRACTITIONER. Edinburgh, 1836.

This is a very neat little manual, of which the junior student or general reader may avail himself with advantage. There is a deficiency of good word-books in our language, the two or three hitherto published being larger than need be, and not so complete after all as their goodly bulk would lead one to expect. The Vocabulary does not make great pretensions, but what it professes to be, it is—a useful book of reference for the student.

MEDICAL GAZETTE.

Saturday, December 17, 1836.

"Licet omnibus, licet etiam mihi, dignitatem Artis Medicæ tuere; potestas modo veniendi in publicum est, dicendi periculum non recuso."

CICERO.

PARENT-DUCHATELET'S WORK.

FURTHER OBSERVATIONS.

It is the merit, or the demerit, of this singular work to have matter in it to attract every class of readers. The statesman (occupied only with serious

subjects), the careless loungeur in the coffee-house, the grave physician, the idle profligate, the kind-hearted lover of his species, and the hardened in vice—all may find something in it to arrest their attention. This variety of information it is, together with the unreserved and candid manner of the author, which has given the last legacy of Duchatelet such vogue in the Parisian salons, and must confer on it notoriety, at least, wherever it circulates.

We gave a brief general view of the production in our last: in our present notice we shall confine ourselves to certain parts of it which are more immediately professional. The third and fourth chapters, for instance, are of this nature; treating expressly of physiological and pathological considerations respecting the prostitutes of Paris; also the sixteenth and seventeenth chapters, on the sanitary measures adopted by the French government in carrying into effect their extraordinary scheme of *organizing vice*, as it has been called.

Some of the questions discussed by the author, relative to certain bodily peculiarities of these public women, are curious, but their interest does not rest there: they involve some very intricate physiological considerations, and in that point of view are deserving of more particular notice.

Of this description is the account which is here given us of the plumpness—the *embonpoint*—of the *personnel* of prostitutes. Excessive fatness even is observed in a great number of these females, and many reasons have been assigned for that condition of body. The most common opinion has been, that it is occasioned by the repeated use of mercury; and several circumstances seem to have contributed to the notion. It has been seen, for example, how quickly women who have been reduced to extreme leanness by syphilis, have

recovered their vigour and health after a mercurial course: it is observed also, that the fattest are among the oldest women of the town, and consequently of the number of those who have been most frequently under treatment; and the conclusion accordingly appears to be rigorously drawn. Nor have *physiologists* been wanting to countenance the supposition. Some have attributed it to the effect of mercury on the lymphatic system; and one wiscacre even went so far as to recommend that animals intended for the market should be fattened by a course of mercury!

Parent-Duchatelet inquired into the phenomenon without begging the question. He first endeavoured to ascertain whether it was a fact that those who took most mercury were most stout: and he soon found that there was no relation whatever between mercury and fatness as cause and effect. He even met with several instances of women who never had contracted syphilis, or who had not had the disorder for many years, yet were of extraordinary obesity. The true cause, as the author suggests, is to be found in the idle inactive life led by prostitutes, together with the abundance of aliment which they consume.

Another peculiarity is the *change of voice* noticed in certain prostitutes. A hoarse masculine tone is contracted, and it has been attributed by some to circumstances connected with their sexual habits—their loose profligate debauchery causing them to lose that delicacy of intonation properly belonging to the female. Our author is not satisfied with this explanation; though we confess we should require stronger reasons than he gives us before we would yield the impression we entertain that there is some connexion between the abuse of the sexual character, and the alteration of the vocal organs: his idea is, that it is owing to repeated drunkenness, and

the chills to which these unhappy wretches are exposed. Here, however, we doubt whether his conclusions have been gathered in his usual cautious manner.

We are obliged to pass over several curious subjects of inquiry—relative to the *colour of the hair and eyes* more or less frequent with prostitutes (considered of course as indicative of their temperament)—their stature and general appearance: these we must leave undisturbed in the volumes, to be explored by readers who take a special interest in such researches. Nor can we dwell on the remarks made by the author respecting the state of the sexual organs in the *prostituées*; the subject is one of much importance in a medico-legal point of view, but cannot well become a topic in our present summary of Duchatelet's labours.

There are few opinions more generally received in the medical world, than that of the *sterility* of prostitutes; but it does not stand the test of fact,—it proves to be an exaggeration. It is true that the number of accouchments which take place amongst them is much less than what might be expected from so many women of between 18 and 25 years of age; but when we find, on referring to the register of the Bureau des Mœurs, from 1817 to 1822, an average of about 51 accouchments annually, while at the Hôpital des Vénériens, at the prison, and the Maternité, the average is above 63, to which we should add the seven or eight deliveries which occur yearly at the private residences of some of the women,—who shall say that prostitutes are sterile? Nay, we ought to take into account a certain number of abortions likewise, not inconsiderable neither, but regarding which the statistical returns are not exact.

In treating of the diseases of prostitutes, the author notices—1, those mala-

dies which are immediately connected with their mode of life; and, 2, those which are common to them with other women. Of the first description are, uterine hæmorrhages, tumors of the external organs, recto-vaginal fistulæ, cancer of the womb, convulsive diseases, and mental alienation. In the second category he places syphilis; and probably to many readers the details given respecting the latter disease will seem the most valuable in the whole work.

We gave some account last week of the police arrangements which exist in Paris relative to the registering and visiting the *filles publiques*. It may be proper to add some further particulars regarding the mode in which the visits are managed. They are conducted by the physicians of the dispensary in three different ways:—

1. The most general practice is for the women to come to the dispensary to be inspected; this they are obliged to do twice a month. The act of inspection is performed with great adroitness: the person examined is placed *sur un fauteuil élevé à dos renversé*. Each medical attendant may thus visit 25 women in an hour, entering the results of his observation at the same time in the registers.

2. At the establishments of the *dames de maison*, visits take place once a week, or four times a month. Each medical man belonging to the dispensary has his particular district. The hour of visiting being fixed, all the women are obliged to be present. The results of the inspection are recorded as in the former case.

3. Another system of visiting takes place at the *depôt* of the prefecture of police. This dépôt is a sort of prison, perhaps somewhat resembling our station-houses. It is a temporary place of detention for persons taken up during the night for robbery, breaches of the

peace, &c.; and among the prisoners are generally found a number of *filles publiques*. These are lodged in a separate room; and it is customary not to suffer them to leave the place till their state of *health* is ascertained. The practice is the more necessary, as these prostitutes are often found to belong to the class denominated *insoumises*, and who have thus escaped regular inspection previously. A surgeon from the dispensary, therefore, makes his visit to the dépôt every morning, and enters the particulars in his journal.

Such were the sources from which M. Parent-Duchatelet drew his statistics of syphilitic disease. From the dispensary registers in particular he was enabled to gather facts demonstrative of the frequency of venereal, as well as of those conditions of the women most apt to contract it. The following table will show some of the results. Suppose we desire to know the frequency of venereal maladies occurring in the whole prostitute population of Paris, comprising those in the prisons and hospitals, we have the following proportions:—

In	average	Infected.
1812		1 in 28
1813 21
1814 19
1816 25
1817 32
1818 38
1819 44
1820 44
1821 52
1823 39
1824 33
1825 32
1827 27
1828 25
1829 29
1830 33
1831 29
1832 47

It will, however, be desirable, in order the better to comprehend the results of the sanitary surveillance, to observe separately the returns made for

those women who live in the *maisons publiques*, as well as for those who though living *isolées*, have always been under observation.

	In <i>Malp.ubl.</i>	<i>Isolées.</i>
1812	1 in 20	1 in 39
1813	... 13	... 32
1814	... 9	... 28
1823	... 8	... 25
1826	... 9	... 23
1828	... 11	... 42
1829	... 22	... 57
1830	... 33	... 57
1831	... 28	... 43
1832	... 26	... 60

How very different these results appear! At first sight it would seem as if the women in the *maisons publiques* were by far the more infected set, and the more dangerous, as tending to spread the disorder. But, as Parent-Duchatelet observes, there are a considerable number of the *isolées* to be deducted from the account—those, for example, who are more properly thieves (*voleuses*), who use the veil of prostitution only for the purpose of carrying on their trade more successfully—also another class “*ces vieilles filles laides décrépites et dégoûtantes, qui se designent sous le nom de manuelles, et qui, par la nature de leur actes, sont très rarement exposées à contracter la maladie vénérienne.*” Such are many of the *isolées*. We should also add, that the girls of this class are visited at longer intervals than the others: they may not be inspected for 20 or 25 days together—while the *filles* of establishments, as we have already stated, are examined regularly once a week.

Among the *insoumises* the population of the infected is enormous, varying from 1 to 5 or 6, to 1 in 3, and even 1 in every 2, annually! How strongly does this at all events justify the expediency of a surveillance!

We have only room for one or two more facts regarding the syphilitic infection. During the month of April,

1832, while the cholera raged in Paris, there appears to have been an extraordinary diminution in the numbers of the infected. As compared with the months immediately before and after, the contrast was striking. In April the return was 1 in 87, while in March it was 1 in 35, and in May 1 in 36: so that the terror of the epidemic may be presumed to have operated very remarkably as an extinguisher of debauchery.

Another circumstance worth observing is the large proportion of prostitutes who escape syphilis altogether. The fact is one which has long been suspected; but every day's experience seems to confirm its truth. Some women are rarely, if ever, diseased; while others are so in rapidly successive attacks, seldom quitting the hospital but to return in the course of a week. The dispensary physicians think that about half the *filles publiques* resist the infection; but Parent-Duchatelet, with reason, doubts the accuracy of this conclusion: he considers it as rather exaggerated.

Other remarkable observations respecting syphilis, its frequency, and its ultimate tendency, we must wholly omit in these our circumscribed limits—taking occasion once more to recommend the perusal of the work itself to those interested more particularly in such inquiries. We could have wished, also, to have made a few more extracts from Duchatelet; but we find it impossible to gratify ourselves in this respect, without neglecting other topics of more immediate concern.

METROPOLITAN UNIVERSITY.

WE announced in our number for Nov. 5 that the King had appended the sign manual to the Charter of this establishment; and we published the draught of the Charter itself, in September last.

The newspapers this week give the

document in its completed form; differing from what has already appeared in this journal, only in two sentences, and in the addition of the names.

We give the sentences to which we allude:—

“And for the purpose of granting the degrees of Bachelor of Medicine, and Doctor of Medicine, and for the improvement of medical education in all its branches, as well in medicine as in surgery, midwifery, and pharmacy, We do further hereby will and ordain that the said Chancellor, Vice-Chancellor, and Fellows, shall from time to time report to one of our principal Secretaries of State, what appear to them to be the medical institutions and schools, whether corporate or unincorporated, in this our metropolis, or in other parts of our United Kingdom, from which either singly or jointly with other medical institutions and schools in the country or in foreign parts, it may be fit and expedient in the judgment of the said Chancellor, Vice-Chancellor, and Fellows, to admit candidates for medical degrees, and on approval of such report by our said Secretary of State, shall admit all persons as candidates for the respective degrees of Bachelor of Medicine and Doctor of Medicine,” &c.

“That the said Chancellor, Vice-Chancellor, and Fellows, shall have power, after examination, to confer the several degrees of Bachelor of Arts, Master of Arts, Bachelor of Laws, Doctor of Laws, Bachelor of Medicine, Doctor of Medicine, and to examine for medical degrees in the four branches of medicine, surgery, midwifery, and pharmacy, and that such reasonable fees shall be charged for the degrees so conferred as the said Chancellor, Vice-Chancellor, and Fellows, with the approbation of the Commissioners of our Treasury, shall from time to time direct.”

The following list of the names of the *corps d'élite* we give exactly as it has been published. There are peculiarities about it worth preserving in their original state: it is a curious specimen altogether, in more respects than one, of the “talent of this enlightened age:” but we shall have more to say about it in our next.

Our right trusty and well beloved cousin,
William Cavendish, Earl of Burlington
(Chancellor.)

The Right Rev. Father in God Edward
Lord Bishop of Durham,

The Right Rev. Father in God William
Lord Bishop of Chichester.

Our right trusty and well beloved Coun-
cillor Henry Baron Brougham and Vaux, and

Our trusty and well beloved George Biddel
Airy, Esq. our Astronomer Royal, and Fel-
low of the Royal Society.

Andrew Amos, Esq. Barrister-at-Law.

Thomas Arnold, Doctor in Divinity,

John Austin, Esq. Barrister-at-Law,

Neil Arnott, Esq. Doctor in Medicine.

John Bacot, Esq.

Francis Beaufort, Esq. Captain in our
Royal Navy, Hydrographer of the Ad-
miralty, and Fellow of the Royal Society.

Archibald Billing, Esq. Doctor in Medi-
cine, and Fellow of the Royal College of
Physicians.

William Thomas Brande, Esq. Vice-
President of the Royal Society.

James Clarke, Esq. Doctor in Medicine,
Fellow of the College of Physicians, and of
the Royal Society.

Philip Cecil Crampton, Esq. Doctor of
Civil Law, Fellow of the Royal Society,
and our Surgeon-General in Ireland.

John Dalton, Esq. Doctor of Civil Law,
and Fellow of the Royal Society.

William Empson, Esq. Barrister-at-Law,
Professor of General Policy and the Laws
of England at the East India College.

Michael Faraday, Esq. Doctor of Civil
Law, Fellow of the Royal Society.

Sir Stephen Love Hammick, Bart. Doctor
in Medicine, Fellow of the Royal College of
Physicians, and Fellow of the Royal Society.

John Stephens Henslow, Clerk, Master
of Arts, Professor of Botany in the Univer-
sity of Cambridge.

Cornelius Hewett, Esq. Doctor in Medi-
cine, and Downing Professor of Medicine in
the University of Cambridge.

Thomas Hodgkin, Esq. Doctor in Medi-
cine.

Francis Kiernan, Esq.

John George Shaw Lefevre, Esq. Fellow
of the Royal Society.

John William Lubbock, Vice-President
and Treasurer of the Royal Society, (first
Vice-Chancellor.)

Sir James M'Grigor, Baronet, Doctor in
Medicine, Doctor of Civil Law, Fellow of
the Royal Society, Fellow of the College of
Physicians, one of our Physicians Extraor-
dinary, and Director-General of the Army
Medical Board.

Richard Rainy Pennington, Esq.

James Quain, Esq. Doctor in Medicine.

John Rideout, Esq.

Peter Mark Roget, Esq. Doctor in Medi-
cine, Secretary of the Royal Society.

Nassau William Senior, Esq. one of the
Masters of our High Court of Chancery, and
Fellow of the Royal Society.

Joseph Henry Gerrard, Doctor of Laws,
Principal of the Bristol College.

Richard Sheepshanks, Clerk, Fellow of
the Royal Society.

John Sims, Esq. Doctor in Medicine.

Counop Thirlwall, Clerk, Fellow of
Trinity College, Cambridge.

James Walker, Esq. Fellow of the Royal
Society, and

Henry Warburton, Esq. member of the
Commons House of Parliament, and Fel-
low of the Royal Society.

NEW BRANCH OF THE PROVINCIAL ASSOCIATION.

WE have much pleasure in devoting a
portion of our space this week to an ac-
count of the meeting at Southampton.
The object of establishing a Southern
branch of the great Provincial Medical
Association is wholly praiseworthy.
When it was attempted some time ago
to institute an Eastern Association, we
expressed our dissent, because we saw
that it was likely to weaken the Asso-
ciation, by converting it into a sort of
merely Western union: we considered
it as a needless, if not a mischievous
division of power—a squandering of
resources which might be better applied.
The projected Eastern establishment has
since, we believe, become what it should
have been from the first—a branch of
the original trunk. To both the Southern
and the Eastern branches, in this
relation to the parent institution, we
heartily wish every success. The grand
central Association has had our best
wishes from the very commencement.

MATERIA MEDICA LECTURES.

MR. PEREIRA has kindly consented to
let us have a new series of his valuable
lectures on Materia Medica, supple-
mentary to those already published in
our last two volumes, and which are
required to render the course complete.
We make this announcement in conse-
quence of applications from many cor-

respondents who were desirous of knowing what we intended to do on the subject. Next week a lecture on *Nux Vomica* will be given, with illustrative engravings.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

MR. EARLE, PRESIDENT, IN THE CHAIR.

Dec. 13, 1836.

A Case of Lithotomy was read, by Mr. W. HILL, of Wotton-under-Edge; the paper was communicated by Mr. Stanley.

THE patient was a boy six years of age, who had all the usual symptoms (rather severely manifested) of stone in the bladder. Mr. Hill performed the lateral operation with the gorget, and removed the stone, which proved to be of the mulberry kind, with a very rough surface.

Considerable bleeding took place from the wound soon after the operation, but it yielded to cold applications; and though it returned on the following night it stopped again. The wound healed in about a fortnight, but the boy was troubled for some time afterwards with various pains and complaints. He felt pain in the glans penis, while making water; the elbow-joint became inflamed; and subsequently the scrotum of one of the testicles. For several months the pain in making water continued, and sometimes was very severe, and attended with calcareous and mucous deposits in the urine. The boy however at length recovered.

The author of the communication seemed inclined to suppose that when irritation produced by the stone in the bladder was withdrawn, the nervous functions became deranged, and gave rise to all the above-described symptoms.

Infrequency of Calculus among Seamen.

A note was afterwards read, from Mr. Copland Hutchison, in continuation and confirmation of some former observations advanced by him in the 9th and 16th volumes of the Society's Transactions. They went to show the great infrequency of calculous disorders in seafaring people of all ages; and the author quoted a curious passage from Aretæus in support of his opinion.

Mr. Hutchison likewise observes, that he has found, contrary to what has been advanced on this subject, that the inhabitants of Scotland are as subject to cal-

culous disorders as their southern neighbours.

We are enabled to give the following more ample account of Mr. Hutchison's note,—the chief points to be established by which were—first, the infrequency of calculous diseases among sailors; and secondly, their prevalence among the natives of Scotland. On the present occasion he confined himself to the former; merely stating in reference to the latter, that his opinion had been confirmed by further evidence, during a recent visit to the North.

To the idea that the complaints alluded to are infrequent among sailors, it has been objected—that this comparative immunity arises not from any influence of the mode of life among sea-faring people, but from the parties not entering it until after the period at which the calculous diathesis becomes developed. This objection Mr. Hutchison met, by stating that many boys are admitted into the navy between the ages of nine and ten (2000 boys are expressly mentioned in the Parliamentary Estimates for the Navy), while the number of operations for stone on persons above fourteen is more than double that on boys of younger age. He also further fortified his position by adducing the authority of Aretæus, who distinctly enumerates a seafaring life (— καὶ πλοῦς καὶ ἡ ἐν θαλάσσει βίωσις)* as among the remedies for calculous affections.

Mr. Hutchison recently applied to Sir William Burnet, Physician-General of the Navy, by whose directions the records of the Naval Hospitals were searched; and it was thus ascertained that only one case of calculus had occurred since 1830, the date of the author's former paper.

Mr. Hutchison concluded by recommending pure air, open bowels, active exercise, swinging, warm clothing, a spare use of vegetables, and iodine given internally, and rubbed over the region of the kidneys, as the best preventive and remedial measures.

MEETING AT SOUTHAMPTON,

FOR THE

FORMATION OF A SOUTHERN BRANCH

OF THE

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

PURSUANT to a requisition signed by nearly one hundred physicians and sur-

* *Medico. Græco. Opera. accurate Kuhn*, vol. xxiv. p. 333. Leipzig, 1828.

persons practising medicine in the Southern Counties, a meeting was held at the Audit House, Southampton, on Tuesday, November 19th, for the purpose of organizing a district branch of the Provincial Medical and Surgical Association. Notwithstanding it was the day on which the high gale of wind occurred, the attendance was most numerous, there being above seventy medical men present from all parts of the district, many coming twenty, thirty, and even forty miles. Amongst the medical gentlemen from a distance were—Dr. Forbes, of Chichester; Dr. Crawford, Mr. Wickham, Sen., Mr. Mayo, Mr. W. J. Wickham, Mr. Smith, of Winchester; Dr. Groves, Mr. Henry Coates, Mr. Sampson, Mr. J. Wynn, of Salisbury; Dr. Towsey, and Mr. Fluder, of Lymington; Mr. Barnett, and Mr. Curtis, of Alton; Dr. Engledue, Mr. Hillard, Mr. Duvey, of Portsmouth; Mr. Beddome, and Mr. Sainsbury, of Romsey; Mr. J. Blatherwick, of Fareham; Mr. T. Blatherwick, and Mr. Andrews, of Titchfield; Mr. Caldwell, and Mr. Warwick, of Millbrook; Mr. Bury, of Farnham; Mr. Eager, of Goidford; Mr. J. P. Graggen, and Mr. Elliot, of Chichester; Mr. E. O. Spooner, of Blandford; Mr. Smart, of Cranbourne; Mr. Smith, of Bishop's Waltham; Dr. Twynham, and Mr. Penkett, of Petersfield; Mr. Lee, of Hythe; Mr. J. Welch, of Christchurch; Mr. Goodwin, of Totton. and of those residing in Southampton, there were—Dr. M'Roberts, Dr. Stodd, Dr. Down, Dr. Oke, Dr. Heuven, Dr. Wheeler, Mr. Maul, Mr. Reele, Mr. Judd, Mr. Stace, Mr. Corfe, Mr. Culebrook, Mr. Fowler, Mr. Simpson, Mr. Bullar, Mr. Clarke, Mr. Ware.

On the motion of Dr. M'Roberts, of Southampton, seconded by J. R. Beddome, Esq. of Romsey, Dr. Forbes, of Chichester, was called to the chair.

Dr. Forbes returned thanks for the honour done him in placing him in the chair, and whilst he disclaimed his peculiar fitness for the office, yet, wishing well to the society, he was anxious to do anything which others might deem calculated to promote its interests. He felt proud to see so numerous and respectable an assembly met on such an inclement day, and many of them at so great a distance from their homes. It was a proof that those present were anxious to emulate their brethren in other parts of England, who had originated and kept up the Provincial Medical and Surgical Association; and a good augury that the medical practitioners of the South were both able and willing to assert the honour and dignity, and to protect the interests of the profession. He had been a member of the Provincial Association from its origin; and

having attended nearly all its meetings, he was deeply convinced of its importance, and was therefore resolved that anything tending to extend its influence should obtain his zealous support. We were met, he said, to-day, to bring this Association home to our own doors, by establishing a branch of it, of which all of us might become members, and at the meetings of which we might all, without journeying far from our own fire-sides, share at least in part in the pleasures and advantages which all who attended the meetings of the parent society must have experienced. He concluded by saying, that as Mr. Wickham, who had the honour of suggesting the establishment of the branch, and who, together with Mr. Bullar, had taken upon himself all the labour of realizing it, was prepared to state the objects for which we were met, and the means which were deemed most proper for accomplishing them, he would not detain the meeting longer, but would take the liberty of requesting Mr. Wickham to bring forward the propositions he was prepared to make.

W. J. WICKHAM, Esq., (of Winchester) delivered the following address.

Gentlemen,—The requisition which has assembled us here to-day will have sufficiently explained to you the objects of this meeting, viz. the extension of the Provincial Medical and Surgical Association through the southern counties—not, indeed, to increase its numerical strength alone, for that is already great—but to form a branch of the parent trunk, which shall impart strength and vigour to its operations, and render that Society, at least in these parts, more effective, and more useful.

In the name of those with whom I have been associated in the attempt to procure this meeting, and for myself, I beg to thank you for the readiness with which you have responded to our call. It is, I trust, no unworthy cause in which we would engage you; and I hope it may not suffer from the poor ability of the individual who is now called upon to address you.

Association, gentlemen, is the great feature of this Institution, a power which, whether exerted for evil or for good, multiplies and combines individual strength and talent, in a ratio proportionate to its extent. It is a power now resorted to in our political conflicts, and is found to be mighty. It is exerted to diffuse and extend the blessings of religion, and is found to prosper. It is adopted on an extensive scale to promote the cultivation of general science, and is found to give an impetus of no ordinary strength to the progress of its pursuits.

I feel satisfied that I have good reason

to congratulate you, and the *medical profession* at large, on the employment of this great power in the service of our department of science.

Societies have existed for many years in our profession—they have been formed in the metropolis and in the provinces—but they have been mostly wanting in that vital property, association; their interests, too, have been local, and therefore their energies have been cramped. It has been reserved, however, for the Society under whose influence we are met here, to incorporate ourselves—to wield this great power with a gigantic strength. It has brought Northumberland into close alliance with Cornwall; it has identified the interests of the eastern with the western counties; it has brought men into *communion* who by their acquirements and labours *only* have been known to each other; it has created friendships in some; it has renewed them in others; it has cemented them in all. It has roused the slumbering energies of many; it has *encouraged* ardent cultivators of our science; it has moreover given a tone to the character of provincial men, which their high and honourable calling demands.

It has been my good fortune only to meet the Association once, at Oxford, last year; I there became acquainted with men of whom I had heard all my life—great men, whose attainments I had long respected, but whose generous and benevolent minds, until then, I knew nothing of. It was there I saw the interchange of opinions between men of high and those of humbler stations, each willing to impart—each eager to receive. It was there I saw a Kidd, a Pritchard, a Hastings, a Carrick, a Johnson, a Forbes, and others with intellects of like capacity, receive the homage of above three hundred of their brethren.

I saw two of our distinguished members receive the honorary degree of the University of Oxford; I saw all participate in the most marked attention and respect which the highest characters in Oxford could offer.

Surely, Gentlemen, it is a matter of congratulation to us *all*, that the provincial members of our profession have thus associated to advance the science of medicine, and to assure for it the position amongst its kindred sciences to which it is justly entitled.

It was at Oxford too that inquiries were set on foot upon the subject of medical attendance on the poor, the result of which is now before the public, in the shape of a report from the Provincial Association.

To that report, which has just appeared, I beg your earnest attention; it is drawn

up at considerable labour, and is grounded on the most authentic information. Its recommendations have been enforced with considerable temper; and the subject treated with the utmost impartiality, “great care having been taken to separate the *bare facts* of each case submitted to the committee, from *expressions* of indignation, which a keen sense of oppression and injury had wrung from the correspondents.”

The report has forcibly shewn that by the existing system the burthen of maintaining the poor during sickness is imposed on the medical profession, and imposed too in the most arbitrary and oppressive manner,—not indeed for the benefit of the poor, but for the imaginary benefit of the “rate payers.”

It further shews that the profession is by the new authorities submitted to insult and degradation; and that the Commissioners have put forth charges which are entirely unfounded, in order, “by impugning the character of the medical body, to reconcile the public to the unjust treatment which they have put upon it, and in many instances successfully.”

The report sets forth the errors of the system of “tenders and competition; which, independently of the professional degradation associated with it, exhibits a narrow-sighted policy on the part of the Commissioners, producing great injustice and cruelty to the poor, by exposing them to the calamities which *must* result from incompetency and neglect from their medical attendants.”

The report recommends that redress be sought, by petition to the legislature, and application to the Colleges of Physicians and Surgeons and the Society of Apothecaries. “Should the Association and the medical body fail in obtaining redress from the legislature, after well-considered and well-directed efforts, the alternative is open to us—either to take a lower station in society, or *firmly to decline any participation in the medical appointments of the new poor-law.*”

The report expresses a regret that there is a want of some “presiding influence over the members of our profession,” to check the wretched spirit of rivalry and speculation, the under-bidding and jobbing, which too frequently is to be found.

In this Association can hope alone rest: this institution seems well suited to raise the moral and professional feeling among medical men in the provinces; and by means of it, more exalted principles, superior aims, and a firmer unity of purpose, will be engendered in the great body of practitioners throughout the country.

It was there also that a benevolent fund

was instituted, for the aid of our poorer brethren: surely it is a matter for our rejoicing that our interests are thus watched, protected, and supported.

It is to a society which seems to me to embrace so much that is excellent, and to involve so little that is objectionable, that I wish to invite your attention: I ask you to join its ranks; and whether you may be disposed to do so in immediate connexion with the Association itself, or whether through this proposed branch, still your services will be acceptable, and your support of value.

The first point which we have to consider, is, how we can best contribute our aid to the Provincial Medical and Surgical Association? In order to carry its objects fully into effect, and to extend its usefulness, I submit that *associating* and *forming ourselves into a Southern District Branch Society*, is the most effectual mode we can adopt to answer these purposes.

The next point for me to show, is what title we may have to engraft ourselves on the Provincial Association, and how far we are fulfilling its objects in so doing.

In 1834, at the meeting of the Association at Birmingham, the following resolution was agreed on, on which the *present extension to district branches* is founded:—

“The Council would recommend, where many members of the Association reside, that occasional meetings of such members take place, for the promotion of the general objects of the Association—namely, the free communication of professional knowledge, and the cultivation of good feeling among the members; the rules for such sectional meetings being left to the consideration of the respective parties.”

Again: at the late meeting at Manchester, it was considered by the Council, and expressed in the proposals for a union of the Eastern Association with the Provincial, that district branch associations would render the operation of the society more effective; and, indeed, if the magnitude and extent of the Provincial Association be taken into consideration, it will, I think, be conceded that its strength will be much increased by the meetings of practitioners from time to time within a smaller sphere. Moreover, Dr. Hastings, the founder and present secretary to the Association, has sent me the terms on which we shall be permitted to unite with the Association, and the privileges which we may expect to derive from it. This letter shall by-and-by be read.

Thus, then, gentlemen, we have as much sanction and encouragement as we can obtain in this stage of our proceedings, for the formation of this Branch Association. It must remain for us to receive the

official admission to it at the next general meeting at Cheltenham.

Propositions for the conduct and regulation of the Society will, in due order, be submitted to you.

The Association being thus constituted, and the seal placed upon it by this day's meeting, let us, gentlemen, go on to carry out its objects to their full accomplishment; let each of us feel pledged to contribute something (and who is there amongst us that has not some original information to impart?); let this association, then, be the treasury in which each may deposit his contributions to medical science. The opportunities of extensive inquiry, or very deep research, are open to but few, but the means afforded in the most limited sphere *should* be embraced. *Facts*, as they present themselves, *should* be recorded by us *all*, and *truths*, wherever they may be discovered, should be treasured up. To accumulate them, and to diffuse them as their value becomes established, is the province of this Association.

I feel a difficulty and a hesitation in requesting your attention to any particular course of inquiry; but I will state a few points to which the parent Society has especially directed its members.

In anatomy, the recent discoveries which have been made have laid open a field of investigation in which there appear before us treasures of inestimable value. In displaying the course of the nerves with the minuteness and fidelity which are the characteristics of Sir Charles Bell's labours, he has greatly extended our knowledge of their functions and their pathology; but still he has taught us that objects of great interest yet remain to be attained, and which it should be *our desire* to search after. Anatomy, too, has of late years unfolded to us the intimate structures of the elementary tissues, which has furnished the pathologist with *abundant* materials, from which *much* has already been gained, but of the fruits of which there *yet* remains much to be gathered. Medical topography and statistical inquiries have received great encouragement from the Association. The labour necessary to collect accurate and useful information on this subject is very great, and the materials do not at first sight appear to afford much of interest. To the reader they are heavy and discouraging; but they *remain* as records which will hereafter prove valuable to the patient inquirer after truth; and as works of reference, will give an accuracy of information which will silence the speculative theorist, and furnish means from which alone just conclusions can be drawn.

Impressed with the importance of the subject, the Council of the General Association has recommended to its members the investigation of *epidemic* diseases.

The record of cases in medicine and surgery, from private sources and from public hospitals and dispensaries, are perhaps the principal means we have of contributing to the advancement of science; and if each case be faithfully narrated, having so much of matter only in the tale as is applicable to a practical deduction, this source of information is highly instructive.

It has appeared to me that too much encouragement has been given to the *simple* narration of cases as they occur in public institutions; our periodicals have teemed with cases merely transcribed from the hospital note-books, without being selected for the value, and without being convertible, in the form in which they have been published, to any practical purpose.

This mode cannot, in my opinion, be too much reprehended: it encumbers the literature of medicine and surgery, and takes the space which should be allotted to more useful matter.

Much benefit might accrue from the communication of the nature and results of severe injuries from accident which have occurred and may occur in practice.

No emergencies in surgery are more perplexing than fractured bones, with their various complications. There are no cases to which the surgeon has to bring a matured judgment and a prompt decision into more immediate exercise; and how are these qualifications to be attained?—they can alone be built on facts accumulated by well-attested results,—not, indeed, from the personal experience of *any one man*, but from the *combined* experience of the *many*.

The question of amputation is often involved in the treatment of these accidents; it is this—are we to sacrifice the limb to save life?—or is the life to be jeopardized by the attempt to save the limb? The principles which guide the decision are for the most part well founded; but I would ask, how have they been formed?—certainly not on the experience, not, I say, on the experience of *any one man*,—not on the result of *any one case*. The experience of *any one man* is too limited to establish a principle on a point so momentous.

You will perceive readily, then, how the communication of cases of this description which may have occurred in your individual practice, would tend to *establish* present principles or to *overthrow* them.

I would ask you not for cases which shall astound and astonish by their extra-

ordinary character,—these are seldom practically important,—but I would ask you for cases on which you have yourselves formed particular opinions, and from which we may *all* participate in the result of your reflections.

As your facts abound,—as your deductions are closely and philosophically formed,—so will your records be in proportion valuable, and your service to science great.

A series of resolutions were then passed in accordance with the principles advocated in the opening speech and address. We regret we have not room to give them insertion, but presume they will be advertised and extensively circulated.

Dr. Oke, Dr. Hennen, and other gentlemen, delivered their opinions at considerable length in supporting certain of the resolutions.

Dr. Forbes was elected President, and Messrs. Wickham and Bullar have been appointed Secretaries.

In the evening about fifty gentlemen dined together at the Star Inn, confirming by a banquet, libation, and all the honours, the very satisfactory proceedings of the day.

A STUDENT'S REMARKS ON MR. WAKLEY—THE SOCIETY OF APOTHECARIES, &c. &c.

To the Editor of the Medical Gazette.

SIR,

ALTHOUGH there is no unseemly boasting in your excellent periodical, nor unmeaning professions for the welfare of medical students—as in the *Lancet*, yet I have always observed, where there is any thing to be effected for them, you take that path which time proves to be the best. Now I have been waiting in anxious expectation to see the working of the Crown and Anchor meeting of last season, and the threatened destruction of the “Blackfriars druggists” put in execution; but as nothing comes of it, I hope you will allow me, through the medium of your journal, to summon your recreant opponent to do battle with the “Hags of Rhubarb Hall,” as he calls them, or ingenuously confess that he has not power to keep his promise. When I *heard* him boast that he thanked the examiners who rejected Mr. S——, as giving him additional power over them, I doubted not but that the days of the Apothecaries were numbered. But as we get older we get wiser, at least I have in

this instance, for I now find out that Wakley's power lies more in the coffee-house than with the influential members of a certain other "House," or with those of the medical profession; for to my surprise, when, about two months back, I went on the same day into two medical libraries in London (neither of them Guy's), and asked the librarians to favour me with the *Lancet*, they both answered, in nearly the same words—Here is the *MEDICAL GAZETTE*, sir; but if you want the *Lancet*, you must go to the coffee-shop, for we do not take it here. Knowing that I was an intruder in the library where I first went, I concluded that this circumstance led to my getting this answer; but I was soon convinced of the contrary by the man coming up to me, and saying—"Any book in the collection you like to see, sir, I shall be happy to get out for you; but we do not take the *Lancet* on account of its scurrilous and useless politics, which distract the students' minds from study, and set them imagining a state of things which will never exist." I now see the truth of this last statement; for had the students, instead of rebelling with such a leader as Wakley at their head, manfully signed a paper in disapprobation of Mr. S.'s rejection, they could not have got less by it than they did by the "Crown and Anchor" meeting: and they would have had the consolation of having acted openly and boldly, while the Worshipful Company would have seen that they might not abuse the students with impunity.

I must say it was a positive injustice on the part of the Hall the rejection of Mr. S., whom I had the pleasure of seeing examined twice, with from thirty to forty other students, who all went up to the Hall, some before and some after Mr. S, without one being rejected; and yet, from the number of questions which he answered with elegance and accuracy, and from the manner in which the other students looked up to him, I at once saw he was the most talented pupil present.

In the *Lancet* for the 29th of October, we see such a silly criticism on the regulations of the Hall respecting apprenticeships, that, did I not believe the gentlemen at the Hall infinitely above transacting any business with Wakley, I certainly should think they had paid him to contradict all his former statements, and that the abusive and useless paragraph which precludes the paper was a blind; for so thoroughly is it at variance with all he has previously given to the world in the *Lancet*, on the subject of the Hall, that it reminds me of "Satan divided against himself," and convinces me that Wakley has no settled principle of action.

In former numbers of the *Lancet* may be read (if any one likes so to waste their time), accounts of oppressive regulations, which pick the pockets of students, by their long stay in London, and by lectures; the necessity of laws to authorize medical men to prepare their own sons and apprentices for examination during their apprenticeship, &c.; and when the Apothecaries make a lenient and very proper regulation, enabling students to appear for examination at the expiration of their apprenticeships, he finds fault with that also. And yet, I have no doubt, if the Hall is done away with (which I trust it will be if they do not reform), and the University substituted to give licenses in pharmacy, we shall see him, like Oliver Proudfoot (in *Scott's Chronicles of the Canongate*), boasting of victories he has never won, and of which he has only retarded the achievement, by appearing in the field.

I must now call the attention of your readers to the abuses existing at Apothecaries' Hall, which I am sure you will insert in your valuable journal; for although I know from experience that you are infinitely above giving students improper advice, which is likely to make them rebel against the powers that our government, in its wisdom, has set over them, yet I am well persuaded that if these powers become abused by the persons to whom they have descended, to the injury of students, their friends, and the country at large, you will not allow it to go on without endeavouring to prevent the mischief likely to ensue.

1st, The lower classes of this country will, in time, become considerably injured by the expenses attendant on a medical education, if allowed to exist as at present, by lessening the number of medical men, and by keeping out those who, from their previous position in society, would be content to attend the poor properly, and be satisfied with such remuneration as they could afford. We all know that most medical men, after four or five years' practice, are no longer solicitous as to who attends the poor in their vicinity (though, to the credit of the profession be it spoken, few cases of neglect can be adduced), and thus, as is natural, the poor fall into the hands of ignorant quacks, who are always endeavouring to ingratiate themselves with them; or into the out-patient department of hospitals, where they fall into the hands of scientific and humane physicians and surgeons; therefore they could not do better, were it not for the necessary exposure to the vicissitudes of the atmosphere, and the disquiet the patient is often put to in being obliged to come from a distance. Yet

at the present time any person, however humble, may procure the attendance of a well-educated medical man at his own residence; but if this three-winter and two-summer regulation of the Hall last long, it will be different this time six years, for it has frightened no less than three youths of my limited acquaintance out of the profession, who were well educated, and likely to become honourable and useful members of the profession; but the waste of so much time was more than they or their friends would submit to. Now it is this three years' course of education I find fault with, as being so great an evil, and not to the expense of lectures; for I consider the lecturers are not sufficiently well paid, where they have small classes, considering the extent of information required of a lecturer.

When I passed the Hall, which was about nine years back, we were only required to attend for six months; but then we studied all the while with diligence, knowing that our time was only just sufficient to become well acquainted with our profession. But now, by what I saw of the state of medical education when last in London, about two months back, young men seem to know that they are compelled to study so much longer than a man of ordinary abilities requires, to learn to be an apothecary, that they procrastinate studying until within a short time of examination, when they go and *grind*. And from conversations I had with several who have lately passed, I am convinced they are not nearly so well informed in medicine and pharmacy as most of the six months' men who studied in 1826 were. Now, as a remedy for this first abuse, I would suggest that the fees for lectures be very considerably increased, so that lecturers may receive from each student in a much shorter time that remuneration which, from their scientific attainments acquired for the use of the students, they have a right to expect. This would give the public interested in medical education a much better opinion of lecturers than they have now; for the general opinion now is—whether true or not, I know not, that the Hall requires this long course of study, that the lecturers may have time to fill their pockets at the expense of the students; the Apothecaries' Society knowing well that they must blend the interest of the medical schools with their own, to keep their power much longer.

2dly. Students complain that they are not treated by the beadle as gentlemen, when they go to register, &c. This is a great evil; and I am told by students, that the manner the Company behave to-

wards them now, if at any time they make inquiry at the Hall during their studies, is such as to put them forcibly in mind of an unopposed country shop-keeper, who, knowing the articles he sells cannot be procured elsewhere, is not over civil to his customers. A little wholesome opposition on the part of the New University will reform this abuse.

3dly. Rejections at the Hall are much more numerous than at any other place of examining students in this country. This is easily accounted for, when we consider that the names of the Examiners are not known to the world by any scientific works, and by their not being among the heads of the profession; hence public confidence would be soon wanting, were it not for frequent rejections; but as it is, the public think having the license implies knowledge, although signed by men quite unknown to science.

4thly. The Latin arrangements at the Hall are very bad; students are allowed to go up and be examined in Celsus and Gregory, before they go up for general examination. This is very much done now, and generally with success: having got through this, they think, and very justly, that they cannot be in danger of rejection in prescriptions, and certainly no one can, if he is able to translate Celsus or Gregory properly; but it is the fact, that many who have successfully got through Celsus and Gregory, have been sent back for six months in prescriptions; therefore the better way for students to prevent such a wanton injury, would be to undergo the examination in Celsus and Gregory when they go up for general examination, when, if rejected in classical Latin, they cannot keep a student back six months; and they would not be silly enough to reject him in the easy Latin of an ordinary prescription, after having immediately before passed him in Celsus.

Such are a few of the abuses which have reached me. I hope these, and others which exist, will be reformed by the Worshipful Company, especially those which keep young men in London so long, wasting their time, in most cases, in vice and idleness. Should they reform, there is no one wishes the Worshipful Company less evil than myself; but should they continue their oppressive regulations, I shall rejoice most heartily if the University puts an end to their pretensions.

I dare say you will think I am endeavouring to make you a radical: nothing is farther from my wish, for I admire your politics, and my opinions always coincide with those of the *GAZETTE*. But there are two things which annoy me in the profession. First, Wak-

ley's scurrility and wrong views of things, which sometimes mislead me; and 2dly, the oppressive regulations of the Apothecaries,—a general complaint, which, it so happens, affects relations of mine considerably,—who very justly say, if we are to be apothecaries, why give us a physician's education? and after our labours and expenses are finished, are we to be satisfied with an apothecary's license? These are the causes of this budget; and as I have not much time for writing, I wanted, as the vulgar say, to "kill two birds with one stone," (Wakley and the Apothecaries.)

Hoping that my friends will not forget to put this in your letter-box, and that you will insert this in the GAZETTE of Saturday next, I subscribe myself

YOUR CONSTANT READER.

Liverpool, December 6, 1836.

I have not put my name to this paper, because it might injure several relations; and I am sure what Wakley says about anonymous letters in his last Lancet, will have no more weight with you, than his endeavour to injure you will have with the profession. He proves by paragraphs from the GAZETTE, that when his "Act" was first made you spoke favourably of it, but when it was brought into use, and found not to answer, you were obliged to discountenance it, as any other theory which sounds well when read, but which is totally useless in practice.

[We have given insertion to the above (slightly condensed) because it appears to be written by a student who makes some sensible remarks with amusing quaintness. At the same time we beg not to be supposed to concur in all the sentiments expressed by our correspondent.—ED. GAZ.]

EXPERIMENTS ON THE VOICE.

HAVING laid bare the vocal organs of an adult male, I raised the larynx to the position it would occupy by the elevation of the voice an octave, being about half an inch, and at the same time minutely observed the position of the lowest ring of the trachea in reference to the sternum. By this operation I found the trachea was raised out of the chest, nearly to the same extent as the larynx had been elevated towards the base of the skull. My next step was to examine whether any change had taken place in the diameter of the tube. Having for this purpose examined the diameter of the trachea in its natural position, I again elevated the larynx to the same extent as before, and found the diameter diminished one third. These

experiments prove that, contrary to the general preconception, the elevation of the larynx shortens the tube independently of the contraction between the thyroid cartilage and *os hyoides*, and at the same time lessens its diameter. The same effects may easily be detected during life by placing the finger on the trachea immediately above the sternum during the elevation of the larynx, when the trachea is found to ascend out of the chest, and afterwards to return to its former position, a movement in which the lungs and bronchia participate. The alteration of the tube in diameter may also be perceived by grasping the trachea with the finger and thumb during the elevation and depression of the larynx.

Such are the principal means provided for adjusting the vibrations of the vocal tube to those of the glottis; but as the variation of length is not sufficient to render the tube capable of adjusting itself to the whole range of tones, the relative tension of its surface supplies the deficiency. The influence of the tension of elastic membranes in modulating the tones produced by them has been very satisfactorily demonstrated by the interesting experiments of Savart, and it is no doubt materially concerned in the analogous phenomena of the voice. The diameter of a tube does not influence the pitch of its sound, but there is an obvious appropriateness in the diminution of the diameter of the trachea as the sound becomes sharper; for experience has taught the makers of wind instruments that the best qualities of tone for the lower notes are obtained when the bore of the instrument is large, and for the higher notes when it is small. The influence of the vocal tube as far as relates to its effects on the key of the voice, is terminated at the *velum palati* by the several perforations of the nostrils, the Eustachian tubes and the mouth. The opinion of Savart, that the mouth modifies the key of the tone, is consequently erroneous. We find analogous acoustic effects in musical instruments; for instance, the lowest joint of the flute, which is six inches in length, having three perforations, when its keys are open lowers the tone of the instrument only half a note. The important distinction between the effects of air passing through the tubes of musical instruments, according as their sides are rigid or membranous, is, that in the former case, as exemplified in flutes, hautboys, &c., the air vibrates independently of the sides of the tube, whilst in the latter, the tube enters into compound vibrations with the column of air.—*Mr. Bishop on the Voice.*

WORKING OF "WAKLEY'S ACT."

To the Editor of the Medical Gazette.

SIR,

ALLOW me to thank you for your able and complete exposure of the inefficiency of the Honourable (!) Finsburian's measure. I feel it is due to you to acknowledge that in a few days after the insertion of my note and your powerful remarks, the overseer of the parish of — called, without any solicitation from me, and discharged the amount of the coroner's order.

The affair speaks for itself, and requires no comment from—Your obedient servant,
CHIRURGS.

Dec. 14, 1836.

NOTE FROM MR. WALKER.

To the Editor of the Medical Gazette.

SIR,

I SHALL be much obliged by your noticing the following *errata*, which appeared in my paper of Saturday last, December 10th.

In the paragraph commencing "Undoubtedly the arrangement of the nerves of the eye, &c.," for "distinction," read "distribution of the nervous filaments." In the last paragraph, for "carried out and perfected by himself," read "myself, &c."

As these errors materially affect the whole, I think it important that they should be pointed out.—I am, sir,

Your obedient servant,

JOHN WALKER.

Manchester, Dec. 12, 1836.

Increase of Burials, as compared with } 1641
the preceding week }

. This being the 52d Weekly Bill, and the last which will be included in the General Bill of the present year, several of the Parish Clerks who had neglected to make their returns in due order, have now reported their deficiencies; from which cause appears the great increase in the Burials.

LECTURES

ON

FORENSIC MEDICINE;

Delivered at the Aldersgate School of Medicine,

BY WILLIAM CUMMIN, M.D.

LECTURE XIII.

Medico-legal consideration of Pregnancy—Cases in which the ascertainment of pregnancy is required by law—The old writ “De ventre inspiciendo”—Jury of matrons—SIGNS OF PREGNANCY—Of conception—Popular signs of pregnancy from suppressed menses, constitutional peculiarities, and enlargement of the person—Important diagnosis from the state of the areola—Discoloration of the vagina—Movement of the fœtus—Quickening—State of the cervix uteri—Ballotement—The auscultatory signs—Conclusions respecting the signs derivable from auscultation.

THE subject which next presents itself to us, in the simple and natural order adopted in these lectures, is pregnancy; and I have only to premise, that in treating it, I am not to be expected to take in that wide range which more properly belongs to the teachers of physiology and midwifery. A view of the subject on so extensive a scale, would embrace a complete history of the changes which occur in the female system from the moment of conception to that of parturition, with an account of the various theories which have been suggested relative to the causes of those changes. But our purpose will be fully answered, if, in our medico-legal capacity, we be enabled to satisfy the demands occasionally made on us in courts of justice, to determine whether, in particular instances, pregnancy exists,—how long,—and whether the fœtus be alive or not.

473.—XIX.

Legal distinctions relative to Pregnancy.—Questions may arise, both in civil and criminal cases, as to the existence of pregnancy. The pregnant state may be feigned, or it may be concealed; and though there are old arrangements still in force, ostensibly for procuring the necessary information on this head, through the agency of females,—“discreet matrons,”—still the inefficiency of such method has often been recognized, and the more usual practice now is to depute professional men to make the requisite inquiries. It is therefore incumbent on us to be prepared for such investigations.

Alleged pregnancy.—The cases in which the medical practitioner may be called upon for his medico-legal assistance, are commonly these:—

1. Where a plea of pregnancy is advanced by a widow, who, soon after her husband's death, in her own name and that of the infant of which she declares herself *enceinte*, lays claim to a portion of an inheritance. In order to provide against any imposition in a matter of so much importance, the old Roman law, *de ventre inspiciendo*, was long ago adopted in this country; a rude and barbarous arrangement for ascertaining the fact of pregnancy. It consisted in a personal inspection, made in presence of a number of “discreet men,” by a number of “discreet women,” who handled the breasts and belly of the examinant, until the whole party were satisfied whether she was really pregnant or not. The writ authorizing this sort of proceeding has been at different times issued: in the reign of Elizabeth there was the celebrated case of Lady Willoughby; and in the last century occurred the case of Sir John Chaplyn's lady, whose three sisters-in-law were to inherit, provided Lady Chaplyn's alleged pregnancy did not prove real.

Even so recently as a year ago, in the case of Mrs. Ann Fox, who pleaded pregnancy, and the probability of a son and

2 F

heir to her deceased husband, the question was argued at large in Chancery, whether the old writ should be issued, as applied for by the heir presumptive; and it would probably have been granted in that case, but that, during the tediousness of the Chancery suit, the lady's pregnancy became so far advanced as to leave little doubt of its reality; a slight surveillance, in the shape of an occasional visit from two matrons and two medical men, was all that was then deemed necessary*.

2. In criminal cases, pregnancy is sometimes pleaded in bar of execution: it forms the ground of a reprieve—in *favorem prolis*—that the innocent may not suffer with the guilty. This law also has come down to us from ancient Rome, where it was held "*quod prægnantis mulieris damnatæ pæna differatur, quoad pariat.*" But before the plea is admitted, it must be made good by the verdict of a jury of "twelve matrons, or discreet women," impanelled from among those who may happen to be present in court: and it must be found, not only that the prisoner is pregnant, but that she bears a *quick* or living child.

Jury of Matrons.—The absurdity of committing so difficult an inquiry to such referees, must be obvious to every one: but there is reason to believe that the practice is worse than absurd—that it is mischievous, and fraught with danger. This had nearly been the case in an instance which occurred at Norwich about three years ago. A female was condemned to death: she pleaded pregnancy, for a respite of her sentence, and a jury of matrons, such as the court-house afforded, was impanelled to try her plea. The jury and the prisoner retired for an hour; but what methods were taken for ascertaining the fact of pregnancy during that time, we know not: we only know that the verdict of the twelve *discreet* women was, that the convict was *not* pregnant. The crime for which the unfortunate woman was tried was murder; her execution, therefore, as the law then required, was to take place on the next day but one after her trial.

It fortunately happened that the attention of two or three intelligent surgeons was attracted to the case. They procured an opportunity of examining the prisoner's person, and came to a very different conclusion from that of the discreet jury of matrons: they found that she was in the sixth month of pregnancy, and that the child was alive. By much exertion, deserving of the highest praise, they were enabled to make a timely representation of the true state of the case to the judge, and the consequence was that a reprieve was granted.

I may add, that, in due time, the correctness of the professional diagnosis was verified; a living infant was brought forth in less than four months.* Ought not this to put an end to the jury of matrons' system for ever? So gross, so almost fatal a blunder, ought surely to stand in perpetual judgment against such a practice. Yet the old law remains, nor is there any likelihood of its being soon repealed. The only chance, therefore, of a rational proceeding, is to be looked for from the discretion of the judges. As they have, in some civil cases, committed the examination of the person to two physicians and two surgeons, selected for the purpose, so it is to be hoped that the custom will be generally followed, and that the female jury may be only known by the next generation, as one of the absurd things which their fathers had so long and so strangely countenanced.

3. It may be necessary, in other cases beside those in which a prisoner is capitally condemned, to inquire into the fact of pregnancy. The magistrate may be induced to grant a mitigation of punishment—the severities of imprisonment or hard labour may be relaxed, should the convict prove to be pregnant.

4. And lastly, the question may be of vital importance in regard to charges of attempted abortion. If pregnancy were denied by the accused, and not shown to exist upon sufficient medico-legal evidence, it is clear that there would be no *corpus delicti*: while, on the other hand, competent professional testimony that the prisoner is positively not pregnant, must put an end to any charge of the sort preferred against her.

Concealed pregnancy.—The detection of pregnancy is in general a difficult task; but especially so when the female is gifted with powers of deceit, and has strong motives for concealing her condition. When the attention of the medical man is not immediately directed to that point, and no circumstances occur to awake his suspicion, as when his services are required for other complaints, nothing is more common than that he should find himself astonished at last by the operations of nature. Ridicule and blame have often been the meed of the practitioner for his supposed simplicity, in thus letting himself be duped, even in cases where no moral presumption could well have been entertained respecting the conduct of his patient. But whether blame justly attaches or not in such cases, I shall not stay to inquire: it is the affair of the practitioner, in the discharge of his ordinary routine duties. We, in our

* MEDICAL GAZETTE, xvi. 697, and xvii. 191.

* MEDICAL GAZETTE, vol. xli. p. 22, and 583.

medico-legal capacity, must never be without our suspicions; we are called in, in fact, only when suspicion already exists, and it is our business to determine whether it be well founded or not.

SIGNS OF PREGNANCY.

What are the signs on which the medical jurist may depend as indicative of pregnancy? It is plain that, for medico-legal purposes, those vague indications on which the vulgar place reliance, and which have been unreasonably called the *rational signs*, can be of little or no use. At the very utmost they may warrant a presumption; but, collected as they must be from extraneous circumstances, or the allegations of the females themselves, they can only be received with the utmost caution. In legal medicine we must have visible, tangible, and audible proofs, and more or less of these in combination, before we attain what would deserve to be considered as conclusive evidence.

Let us first suppose the pregnancy to be uterine, and that the changes consequent on the development of the embryo proceed in their ordinary or normal course. Extra-uterine pregnancy, and the irregularities attendant upon that and other conditions, may afterwards be more conveniently noticed.

Question of conception.—It has been thought that soon after conception some appearances indicative of the occurrence of that state might be observed. But it would be idle to mention the fallacious and ridiculous signs which were once depended on by medical authorities, and still are by gossiping people of either sex. They were almost all grounded on certain sensations supposed to have been experienced by the female—a sudden chill, excessive languor, &c.—after increased sexual enjoyment. The question, however, is seldom or never proposed to the medical jurist, to determine the fact of recent conception in the living female. Where a woman has died presently after an alleged connexion—from poisoning or other injury—it may be possible to gather from the state of the organs of generation some strong presumptions, which may greatly corroborate the circumstantial and moral evidence. A deciduous membrane may be found lining the cavity of the uterus; a mucous-looking fluid resembling semen may be found in that cavity, as well as perhaps in the fallopian tubes; and probably a corpus luteum may be detected in one or other of the ovaries.

I have here [exhibiting it] a very beautiful drawing made from nature by my accomplished colleague, Dr. Hope. It represents the state of the vagina, uterus, and its appendages, in a young female

who poisoned herself. From the history of the case, and an evidently recent laceration of the hymen, it was probable that impregnation had taken place within a very short period. In the uterus, which is somewhat larger and redder than in the virgin state, was found a quantity of gelatinous matter, with that dark coagulated blood in small flakes which John Hunter describes as belonging to incipient infestation. Both the ovaries appear turgid with very dark blood; the section of the left displays a corpus luteum, with a T-shaped scar in the corresponding surface, through which the ovum had probably escaped. In the right ovary may be seen an ovum apparently mature for impregnation. Both the fallopian tubes were filled with a fluid, whiter and more opaque than mucus; and in the uterus was a similar fluid, but more gelatinous and transparent. It would have been interesting had this fluid been more particularly examined as to its physical and chemical characters. I shall have occasion to refer to this drawing again*.

Enumeration of the signs of pregnancy.—In enumerating the ordinary symptoms of the pregnant state, we cannot wholly overlook those which are properly esteemed vulgar, although they be so little worthy of notice for the purposes of forensic medicine. The first three among the following are of this kind—viz. suppression of the menses, morning sickness, and enlargement of the breasts and belly.

1. *Suppression of the menses.*—The fact of the non-appearance of the catamenia at the usual period can be of little value in a medico-legal point of view; yet, as a symptom of pregnancy, it is the one which commonly makes the strongest impression on females themselves, and from which they usually calculate the date of their gestation. But it is obvious that suppression of the menstrual discharge may be owing to a variety of circumstances beside pregnancy. At a certain time of life it indicates a total cessation of the functions of child-bearing; and, on the other hand, women have been pregnant without ever having had the menses. Women again may menstruate more or less during the period of pregnancy. Heberden mentions a lady who had borne several children, yet had never ceased, either during her pregnancy or nursing, to menstruate regularly. Denman, on the contrary, insists strongly on the sign, and considers it as a *sine qua non* of the pregnant state.

2. *Nausea, &c.*—The concomitant circumstances of morning sickness, depraved appetite, irregular aches and pains, sharpness of the features, &c., may be classed

* See an engraving from it in next lecture.

together as a set of vague signs, which acquire any value only when strongly corroborated by collateral facts. It is true that most pregnant women do experience many of these symptoms during pregnancy; but we must recollect that they may all originate in totally different causes, and are sometimes not observable during the whole period of gestation. As to sharpness of the features, it is certainly peculiar, but is chiefly observable only in the later months, when the abdomen is very large—the integuments of the face being then affected, even drawn down by the distension and weight of the part: it is that condition which the gossips call being “all mouth and eyes.”

Dr. Dewees lays great stress upon a sign which he holds to be infallible, and that is, a peculiar kind of salivation which sometimes takes place: the pregnant woman spits frequently, and in such a way as to justify the remark that she is “spitting cotton.” In this country, or at least in Ireland, as we shall see by a trial to which I shall probably refer in the sequel, the term is not very different, and evidently applies to the same thing: the woman is said to be spitting “long spits.” But these are matters obviously of little or no practical importance to the medical jurist.

3. *Enlargement of the breasts and abdomen.*—The breasts sometimes become unusually large; and are popularly noticed as symptoms of pregnancy. Should this enlargement be contemporaneous with other well-marked signs, it may have some value; but the breasts so frequently sympathize with the uterine system, and, indeed, are so invariably affected in their size and consistency by accumulation or suppression of the menstrual fluid, to whatever cause that circumstance may be owing, that it can clearly be only accounted as a collateral and very vague sign. Even though there be milk in the breasts, it is far from being a certain sign *per se*; for virgins are known to have had a secretion of that fluid; and old women, too, long after the cessation of child-bearing; nay, men have had an abundant flow of milk in their breasts, sufficient at least, according to some remarkable narratives given us on the authority of the celebrated Humboldt, and Captain Franklin, in his *Overland Journey*, to suckle their own children.

The abdomen.—With respect to enlargement of the abdomen, that most popular of the visible signs of pregnancy, we must take care not to be deceived. In the first place, are we sure when we observe this increase of size that it is owing to an enlargement of the uterus? and secondly, are we quite sure

that such enlargement is owing to the presence and the development of a *fœtus*? These are points on which we must have some assurance before we can infer the fact of pregnancy.

The phenomenon may result from dropsy—simple, or encysted, or ovarian—from tympanitis, or other affections, with the diagnostic signs of which we ought to be sufficiently well acquainted not to confound them with the effects of pregnancy.

Enlargement of the abdomen in uterine pregnancy is generally uniform and symmetrical—an appearance which serves to distinguish it from that which is consequent on extra-uterine pregnancy, or dropsy of the ovaries. The degree of augmentation which is observed to characterise the several stages of pregnancy is worth attending to.

No very obvious enlargement of the abdomen can probably be observed until after the completion of the fourth month. About this time, say between the fourth and fifth months, the belly begins to be globular, the skin appears distended, and the fundus uteri is found to correspond to the middle point between the umbilicus and the pubes. On the completion of the sixth month the fundus has reached about the height of the umbilicus. The augmentation of volume is now very striking. About the seventh or eighth month the fundus is perceived to be higher, considerably so in many cases, than the navel. Towards the early part of the ninth month the fundus even reaches the *scrobiculus cordis*, though, shortly before parturition, there is a manifest sinking of the parts to about the volume they occupied in the course of the eighth month.

The state of the navel ought not to be overlooked. It undergoes changes in its figure during the regular enlargement of the abdomen; it is ultimately thrown outwards, first becoming gradually obliterated, or at least levelled with the surface of the belly; and during the latter months assuming the form of a prominent boss.

4. *Areola.*—The preceding signs are, as I have said, more or less fallacious: those, however, which I have now to notice are deserving of a higher degree of attention; and the first of these is the peculiar state of the nipple, and of the integument around it, constituting the *areola*.

The appearance of the areola as indicative of pregnancy, has long been observed by medical men, and some have been known to place great reliance upon it. Dr. William Hunter is said to have considered it as a master-sign; and a story is told of his having pronounced a woman pregnant, whose body he merely happened to see in the dissecting-room; and he persisted in his assertion, though it was objected to

him that the hymen was unruptured: his diagnosis, however, was formed from the appearance of the areola, and his opinion proved to be fully justified by the subsequent inspection of the internal parts.
